In a number of studies, concerns have been identified by online support group members around the challenges of assessing the credibility and trustworthiness of information exchanged (Sillence, 2010). For example, it might be the case that some of the messages posted to an online support group may not in fact be from genuine patients living with a particular long-term condition. For example, it may be that an individual makes a series of postings to an online support group in order to advocate a specific treatment. In such a scenario, it may be that this individual is actually an employee of a drug company or some other organization who has a vested interest in the particular product being promoted (Coulson, 2013).

When an individual member within an online support group posts a message offering information or advice, it is not uncommon to see other members also replying to share their experiences and these responses may be helpful to the individual in terms of determining the credibility of the original information or advice. It has been argued that incorrect or misleading information may be more of a problem within online support groups with low levels of activity (Hwang et al., 2007), but broadly speaking it appears that the actual number of messages which contain incorrect or misleading information is low (Esquivel, Meric-Bernstam & Bernstam, 2006).

Delayed Feedback

Another disadvantage associated with online support group is delayed feedback (Wright, 2002). Although participants can log in and post messages at virtually any time of day, in comparison to face-to-face groups there may be a considerable time lag before the individual receives a response from other participants.

Individual Differences in Online Support Group Use

Socio-Demographic and Psychosocial Characteristics

Empirical data from Internet user surveys suggests that individuals who seek health-related information and support online tend to be white, female, well-educated, of a younger age and in employment (Eysenbach, 2003; Im et al., 2007). There is some evidence to indicate that these factors are also associated with participation in online support groups (Owen et al., 2010). For example, in a recent survey of cancer sufferers, Im et al. (2007) found that patients accessing online groups were typically middle-aged, well-educated, female and middle class. Similarly, Hoybye et al. (2010) found that cancer patients participating in online support groups belonged to higher socioeconomic groups compared to non-participants. Another recent survey of Internet use among individuals with HIV/AIDS, also revealed that frequent users of online support groups were more likely to be female, younger and single when compared to infrequent or non-users of online support groups (Mo & Coulson, 2010).

The association between patient's demographic characteristics and health-related Internet use may reflect barriers to Internet access among certain groups of people. For instance, individuals who are educated and in employment, may be more likely to have easier access to Internet resources compared to those who are unemployed with a lower educational record of attainment. Shaw

et al. (2006) examined whether demographic variables would predict participation in online support communities when barriers to Internet access were removed. A group of breast cancer patients were therefore provided with free Internet services, computer hardware and IT training. As hypothesised, the study found that demographic differences in participation were diminished. Nevertheless, the factors that predicted higher levels of participation were found to include having fewer breast cancer-related worries, a positive relationship with doctors and higher levels of social/family well-being. This implies that a range of psychosocial characteristics may influence participation in online groups.

However, there is comparatively little research specifically examining the relationship between patient's psychological characteristics and health-related Internet use, particularly the use of online support groups. Furthermore, the findings from the few studies (e.g., Fogel et al., 2002) that have addressed psychosocial factors are mixed. While some studies suggest that individuals turning to online groups report high levels of social support from offline relationships (Fogel et al., 2002), others have found that individuals seek online support when offline support is perceived as inadequate. For example, in a study comparing women with breast cancer who use the Internet for support and women with breast cancer who do not, Winefield et al. (2003) found that women using the Internet were significantly less satisfied with support from their family and were more psychologically distressed than non-users. Conversely, an Internet use survey conducted by Ybarra & Suman (2006) reported that those individuals who did not use the Internet for health-related purposes were more likely to report being unhappy or lonely. However, recent surveys by van Uden-Kraan et al. (2009) and Hoybye et al. (2010) found no relationship between psychological well-being and health-related Internet use among arthritis, cancer and fibromyalgia sufferers.

Since most studies employ cross-sectional designs it is difficult to determine causality. The

exact nature of the relationship between social support, distress and participation in online support groups is therefore unclear.

Level of Interaction

To date, little is known about the reasons why some members become active contributors of online groups, while other members are less involved. There are however several ideas which have emerged in the literature. For example, Kollock (1999) proposes three key motives to explain why some individuals contribute to an online group. Firstly, anticipated reciprocity, where an individual is motivated to offer help and support in the expectation that they will also receive the same support and information when required. Secondly, for a sense of efficacy, where members will contribute useful information or support to the other members in the belief that they are having a valuable impact on the group, which may help to promote their own self-efficacy. Thirdly, to gain increased recognition and help build up a reputation within the online group.

Another approach for understanding participation in online group is through the 'uses and gratification' model (Blumler & Katz, 1974). The basic premise of the model is that people are motivated to use mass communication in order to gratify a range of needs or goals. Thus, when considering level of participation in online groups, the theory would suggest that members are motivated to be passive or active participants depending on which activity offers the best means of meeting their needs. For example, an individual who wishes to obtain information whilst also maintaining anonymity, may find gratification in 'lurking' (Nonnecke & Preece, 2000). In comparison, individuals who wish to connect with other participants and develop new friendships will be motivated to take a more active role in the online group. Although the theory offers a useful way for examining participation in online groups, it has not yet been extensively applied to understand participation.

Posting Messages or 'Lurking'

Individuals who access online groups but do not participate are referred to as 'lurkers'. Lurking describes the act of 'reading messages posted by others on electronic spaces, without also posting one's own messages or in any way signalling one's vicarious observation' (Walther & Boyd, 2002, p168). It is estimated that 'lurkers' make up the largest group of individuals using online groups (Burnett, 2000).

Despite the prevalence of lurking, little is known about the online experiences of 'lurkers' and their motives for visiting online groups. This is in part due to the difficulty of identifying and accessing the views of individuals who choose to remain entirely anonymous. In an attempt to redress this, Preece, Nonnecke and Andrews (2004) surveyed 219 'lurkers' from 375 MSN bulletin boards to explore their reasons for not posting. The most frequently selected reason for lurking was 'just reading/browsing is enough' followed by 'still learning about the group', 'shy about posting', 'nothing to offer' and 'no requirement to post.' It was observed that many individuals lurked while familiarising themselves with the dynamics and norms of the group. Others commented that by not posting their views they felt they were being helpful (e.g., not pretending to be an expert).

Attention has also focussed on investigating differences between the attitudes of 'lurkers' and posters. Research findings indicate that posters perceive a greater sense of group membership in comparison to 'lurkers', who appear to be less positive about the benefits of group participation (Nonnecke, Andrews & Preece, 2006; Okleshen & Grossbart, 1998; Preece, Nonnecke & Andrews, 2004). It has been suggested that this might arise from the fact that members who do not actively participate in online discussions will often feel like distant outsiders who are simply observing a separate group of people interacting.

Some authors (e.g., Walther & Boyd, 2002) argue that individuals reading messages within health-related support groups are, on the contrary,

likely to feel empathy with the stories they read due to their shared experiences. As a result, these 'lurkers' may perceive a stronger sense of membership and connection to the group (Preece, 1999). Walther and Boyd (2002) propose that patients lurking in online support groups will also derive similar benefits to that of active participants. They argue that since patients can obtain information, support and validation of their feelings of stigma through reading other people's messages and without having to contribute anything themselves, lurking may be as beneficial as active participation. Lurking can also function as a helpful way for patients to find answers to frequently asked questions without overloading the group with a repetition of earlier queries.

However, there remains a scarcity of empirical work exploring the phenomenon of lurking in the context of health-related support groups. Recently, van Uden-Kraan et al. (2008b) investigated self-reported differences in the benefits associated with participation between 'lurkers' and posters in various online patient support groups. Results indicated that both 'lurkers' and posters gained a range of benefits from the online groups including feeling better informed, enhanced self-esteem, feeling more confident with physicians, and improved acceptance of the disease. Thus, offering support for Walther and Boyd's argument. However, in line with findings from other types of online groups, the study found that 'lurkers' were significantly less satisfied with the online group compared to posters and had poorer social and mental well-being. This suggests that although individuals can benefit from reading messages, individuals who lurk may be less satisfied with their online experiences than active participants and have poorer psychological well-being.

The Nature of Online Communication

What Do Members of Online Support Groups Discuss?

Research which has considered what members talk about within online support groups has provided

either a broad overview of discussion areas, such as symptoms, diagnoses, treatments and medications (Finn, 1999; Haker, Laubler & Rossler, 2005; Mursch & Behnke-Mursch, 2003; Perron, 2002; van Uden-Kraan et al., 2008a) or a richer insight into the specific health-related issues. A number of broad, recurring themes emerge from these studies. First, they demonstrate the importance of being able to communicate with others who can understand them and have been through similar experiences. Second, they demonstrate how people benefit from having a safe environment where they can vent and express their true feelings without the risk of hurting others or damaging social relationships. Third, they highlight the frustrations caused by misconceptions about what each illness is and how it affects sufferers. Fourth, the information, social support and advice shared within these groups can have an important impact on members by helping them to feel less alone and develop more effective coping strategies to overcome the issues unique to each illness.

Understanding the Therapeutic Processes Involved in Online Support Group Communication

There is a growing body of research which has attempted to understand the potential therapeutic processes at play within online support groups. These include: self-help mechanisms, social support and self-disclosure.

1. **Self-Help Mechanisms:** A small number of research studies have shown that online support groups can provide many of the therapeutic exchanges that occur in face-to-face self-help and support groups (Finn & Lavitt, 1994; Finn, 1999; Haker et al., 2005; Perron, 2002; Salem, Bogat, & Reid, 1997; Schielein, Schmid, Dobmeier, & Spiesl, 2008; van Uden-kraan et al., 2008a; Weinberg, Uken, Schmale, & Adamek, 1995). For example, Weinberg et al. (1995) investigated the presence of therapeutic factors in an online support group for women with breast cancer.

The study was guided by a range of factors which are thought to influence the process of change and recovery among patients in group therapy – universality, altruism, instillation of hope, imparting information, catharsis, group cohesiveness, interpersonal learning, imitative behaviour, developing social skills, existential factors and the corrective recapitulation of the primary family experience. Results revealed that women perceived the instillation of hope, group cohesion, and universality to be the most prevalent therapeutic factors. These factors were also moderately correlated with the perceived helpfulness of the group. Perron (2002) coined the term ‘self-help mechanisms’ to describe the parts of messages that facilitate the development of supportive or helping relationships among members of a group. Their analysis of communication in an online community for caregivers of people with a mental illness found that similar to face-to-face groups, members of the online group employed a range of self-help mechanisms. Specifically, self-disclosure and the provision of information or advice were found to be a central focus of many of the messages posted to the online group. Similar findings have been observed in studies examining self-help mechanisms within other illness support groups, for example, infertility (Malik & Coulson, 2010).

2. **Social Support:** A larger number of studies (e.g., Braithwaite et al., 1999; Coulson, Buchanan & Aubeeluck, 2007) have focussed on examining the type and nature of social support exchanged within online groups. Some of these studies employed content analyses as a means of quantifying the prominence of different categories of social support (e.g., Coulson, Buchanan, & Aubeeluck, 2007). One study analysed messages posted to an online disability support group for the presence of 5 categories of social support – informational, emotional, network, esteem

and tangible aid (Braithwaite et al., 1999). Of the 5 categories it was observed that messages exchanging emotional support, followed by informational support were most prominent, whilst tangible assistance was the least common category. The primary focus of these support messages appeared to relate to life functions affected by disability. For instance, informational support typically involved sharing advice and suggestions to help members tend to their self-care and house-keeping needs, while network support aimed to reduce limitations on mobility and access to others. In an analysis of messages posted to an Irritable Bowel Syndrome bulletin board, Coulson (2005) also noted that tangible assistance was the least visible category of social support, while the exchange of information concerned with symptom interpretation, illness management and interactions with health-care providers were the most common forms of support. Overall, research suggests that informational and emotional support appear to be the most prominent exchanges in health-related online support groups. Alongside the prevalence of emotional and informational support, a number of authors also identify features of online support that appear to be relatively unique to this format. For example, humor, personal narratives/journals and poetry have all been found to play an important role in supportive exchanges taking place in various online groups (Braithwaite et al., 1999; Hwang et al., 2010; White & Dorman, 2001). Indeed, Braithwaite et al. (1999) found that many members of a disability community joked about their own problems as a method of conveying empathy and in some instances used poetry to express emotional support.

3. **Self-Disclosure:** Along the development of strong interpersonal relationships, evidence suggests that Internet behaviour is also characterised by high levels of self-disclosure. Self-disclosure can be defined as the act

of revealing personal information to others. Computer-mediated discussions are thought to contain higher levels of disclosure compared to face-to-face discussions. This phenomenon is also apparent within online support groups (Barak & Gluck-Ofri, 2007). One factor that might explain the high levels of self-disclosure observed in these online groups is the anonymity associated with computer-mediated environments. Online support groups provide individuals with the opportunity to keep their identities entirely anonymous, this may encourage certain individuals to disclose information that they may otherwise feel uncomfortable discussing with others due to the possibility of a negative reaction. As Caplan and Turner (2007) point out, the anonymity offered by these groups may help to 'establish a safe and secure environment in which participants are willing to discuss deeply personal and upsetting matters' (p. 989). Tichon and Shapiro (2003) argue that self-disclosure plays an important role in the elicitation and provision of support. In their examination of messages posted to a group listserv for siblings of people with special needs and learning difficulties, self-disclosure was used in three distinct ways. Firstly, self-disclosure was used by participants to elicit support and start a relationship with other members, for example members would often share concerns and problems with the group to generate a discussion about ways to cope with their problems. Second, self-disclosure was used by support providers to demonstrate that successful coping is possible through disclosing similar experiences where they had successfully coped. Finally, self-disclosure was used to share social companionship with other members.

4. **Psychosocial Benefits of Participation:**

To date, there has been a lack of outcome research (Eysenbach et al., 2004) evaluating the efficacy of health-related online support

groups. Most quantitative studies in the literature focus on professionally developed online support groups or comprehensive computer support programmes. Comprehensive support programmes typically incorporate a wide array of interactive features including question and answer functions, decision-making and problem-solving aids, encyclopedia reference materials and individually tailored behaviour change support. Two of the most extensively researched comprehensive computer support systems for chronic health conditions are the Comprehensive Health Enhancement Support System (CHESS) and ComputerLink. The basic format of these interventions have been tailored to meet the needs of individuals suffering from various health conditions such as Breast cancer, Prostate cancer, Alzheimer's disease, Asthma and HIV and AIDS, and for patients from different socio-demographic backgrounds. Randomised controlled trials and observational studies assessing the impact of these computer systems indicate that usage may be associated with a variety of positive outcomes including improved emotional well-being and quality of life, more efficient use of health care systems and improved ability to cope (e.g., Gustafson et al., 2005; Gustafson et al., 2008). In addition, a number of studies note that the communication features of the support systems appeared to be the most heavily accessed functions (Gustafson et al., 1994). This suggests that participants may particularly value and benefit from computer support interventions that offer the opportunity to interact with other patients. While these studies show that computer-mediated patient support interventions can have beneficial effects for individuals, they tell us very little about the effectiveness of the millions of "natural" online support groups found on the Internet. Most studies evaluate complex interventions with a range of different components mak-

ing it difficult to distinguish the stand alone effect of online communication and peer-to-peer support. However, in a systematic review of the effects of health-related online groups, Eysenbach et al. (2004) found only six studies that evaluated pure peer-to-peer online communication. Most of these studies contained relatively small samples sizes and no comparison group, thus limiting the generalisability of the findings. The review therefore concluded that there was a lack of robust evidence for the psychological and health benefits of peer-to-peer online groups. Despite this, there is a growing body of qualitative literature which suggests that use of an online support groups can be associated with a range of positive psychosocial benefits for patients, particularly in the context of self-management behaviours (Allen et al., 2016).

5. **Empowerment:** More recent evidence suggests that participation in online support groups can have an empowering effect on patients suffering from physical and mental health problems (e.g., van Uden-Kraan et al., 2008c). The term empowerment describes a process through which people gain greater mastery and control over decisions and actions affecting their lives. In the context of health care, empowerment can reflect an increased confidence in one's ability to manage their condition, the ability to access appropriate health information and greater control over health-related decision-making and interactions with healthcare providers. The exact nature of patient empowerment however is complex; various factors can have an empowering effect including a patient's skills and knowledge, trust, locus of control and a reduction in feelings of hopelessness, isolation and oppression (van Uden-Kraan et al., 2008c). Different patients may also have different experiences and perspectives regarding empowerment. Furthermore, empowerment not only reflects an individual's

sense of control and efficacy but can also occur at the group and community level. There is also a distinction between empowering processes (i.e. the process through which individuals take control of their life) and empowering outcomes (i.e. the psychosocial consequences of empowerment). The majority of research documenting empowerment in online support groups has focused on exploring the empowering processes that take place in messages exchanged between participants (Finn, 1999; Perron, 2002; Sharf, 1997). For instance, in a discourse analysis of communication in an online breast cancer mailing list, Sharf (1997) reports that the online group allowed women to express feelings of grief and depression surrounding their experience of breast cancer whilst simultaneously offering a unique source of information and emotional support. This not only resulted in enhanced decision-making but also helped the women meet new challenges associated with breast cancer and transform their feelings of negativity into optimism.

CONCLUSION

Relatively little work has been conducted to examine the extent to which the empowering processes that occur online lead to empowering outcomes. Some qualitative studies have addressed this issue through exploring empowerment from the perspective of the patient. Buchanan and Coulson (2007) found that dentally anxious individuals accessing an online support group felt that the guidance, encouragement and shared experience offered by the online community empowered them to try to conquer their own fears. The support available from the group also led to a growth in confidence about disclosing dental anxiety to dental professionals. In another study, van Uden-Kraan et al. (2008c) asked participants using online breast cancer, arthritis and fibromyalgia support

groups about the full range of both empowering and disempowering processes that occur online. Results revealed that empowering processes included emotional support, information exchange, recognition, sharing experiences and helping others. These processes appeared to bring about a number of empowering outcomes namely feeling better informed, a greater sense of confidence about their treatment and interactions with health care professionals, improved acceptance of the disease, increased optimism and self-esteem and greater social well-being.

FUTURE RESEARCH DIRECTIONS

Over the past decade there has been a rapid growth in the number of studies which have considered peer-to-peer health-related online support groups. Despite this, there has been a notable lack of well-conducted randomized-controlled trials therefore there is an urgent need to redress this situation, particularly in the context of long-term physical health conditions. Beyond this, however, there is a need to more fully understand predictors of engagement with online support groups, factors impacting on levels of engagement as well as their linkage with relevant clinical outcomes. More broadly, if we are to fully understand and realize the potential of peer-to-peer health-related online support groups then a multi-disciplinary research perspective must be adopted.

KEY TERMS AND DEFINITIONS

Deindividuation: When a person has a lower sense of self-awareness and 'loses' themselves within a larger group.

Lurking: When an individual does not actively post messages to a discussion forum but rather passively reads messages.

Online Support Group: A collection of individuals who come together online to engage in mutual support in the context of health and illness.

Self-Help Mechanisms: The therapeutic processes that may help oneself to address a challenge, crisis or difficult.

Social Support: The perception and actuality that one is cared for, has resources available from others and is part of a support network.

H

Software Evaluation From the Perspective of Patients and Healthcare Professionals

Rui Pedro Charters Lopes Rijo

Polytechnic Institute of Leiria, Portugal

Domingos Alves

University of São Paulo, Brazil

INTRODUCTION

Healthcare software evaluation is a complex process. Specifically, in the health information systems, focusing on the patients' health and on the healthcare professionals' motivation is particularly important.

Doctors, nurses and other healthcare professionals use software that indirectly affects the patients. Does software improve the patients' health, their satisfaction, or the healthcare professionals' commitment/job satisfaction? How can the impact of an information system be measured from the perspective of the patients, the doctors, the nurses or the supporting staff? Some relevant efforts have been made in the last years to measure healthcare software impact. Nevertheless, the decision to extend a study to different fields may lead to many difficulties as far as its conclusions are concerned. By identifying the research questions and the most relevant works, as well as indicating the open research issue, this article is a revision of the literature on the subject. This work may be expected to be useful to all those wishing to contribute by their research in this field. The article provides a historical perspective of the field, followed by the main research works, their goals, instruments and key results. A thorough discussion of the results, advances and challenges will also be developed, finishing the manuscript with fruitful research directions.

It is believed that this article will be of great value for those who need a solid insight in the

field and want to contribute for advances in the research questions identified.

The next section introduces the concepts related with the evaluation of the software, patients' satisfaction evaluation, and the healthcare professionals' satisfaction. The following section presents the dimensions of evaluation, tools and approaches used, ending with a discussion of issues and challenges of the assessment of patients' and healthcare professionals' satisfaction. Solutions and recommendations are preceding the discussion of future and emerging trends. Finally, the last section provides discussion of the overall coverage of the chapter and concluding remarks.

BACKGROUND

According to the World Health Organization (World Health Organization, n.d.), e-health can be defined as the providing of services and resources per electronic means either for health professionals, health consumers or for health systems management. Software plays in this way a central role in the healthcare systems because it can interact with the patients or doctors, or being embedded software in medical instrumentation, and other healthcare-oriented life-critical systems. Software is becoming more pervasive in all facets of medical device design and development. As transitions from hardware to software controls occur, there is a growing need for formalized software assurance processes (Cooper & Pauley, 2006).

Table 1. Challenges encountered at the intersection of healthcare services, information systems and evaluation technologies (Alalwany, 2010)

The Research Field	The Challenges Encountered
Healthcare services	• Healthcare services are characterized by having many stakeholders who are working in different disciplines and pursuing different goals. • Healthcare services are dictated by complex regulations. • The medical knowledge is an enormous and dynamic field. • The main aspects of medical knowledge require an interactive environment to be transferred or practiced.
Information Systems	• The multiple perspectives involved. • The difficulties of quantifying benefits. • The nature of information systems investments is changing both in terms of technological capability and the benefits they can deliver, as well as in terms of diffusion in most aspects of society. • Consider the social and technical context of use.
Evaluation Methodologies	• The limited experience of using methods. • The unfamiliarity with evaluation techniques. • The difficulty in interpreting results.

The use of the modern information technology in health offers tremendous opportunities: 1) to reduce clinical errors, e.g., medication errors, diagnostic errors; 2) to support health care professionals, e.g., availability of timely, up-to-date patient information; 3) to increase the efficiency of care, e.g., less waiting times for patients; 4) or even to improve the quality of patient care (Elske Ammenwerth, Gräber, Herrmann, Bürkle, & König, 2003)(Walker et al., 2005). According to Alalwany (2010), e-health supports disease allows people to better manage their own health and provides more accessible and consistent healthcare services, besides improving the efficiency of healthcare systems. Despite the opportunities, e-health presents some challenges namely considering that modern information technology systems are costly (Drouin, Hediger, & Henke, 2008)(Deloitte Touche Tohmatsu Limited, 2015) and that their failures may cause negative effects on both patients and staff. Adopting e-health applications is also highly complex. Finally, the privacy and security concerns in e-health applications are other key challenges. Therefore, a rigorous evaluation of IT in health care is recommended (Brender et al., 2013) and of great importance for decision makers and users (Kaplan & Shaw, 2004). Evaluation is likewise of some importance considering the high rate of failed IT projects in public sector where 35 percent of IT government projects have

been classified as total failures, and 50 percent as partial failures (Heeks, 2006).

As for evaluation it can be defined as the decisive assessment of defined objects, based on a set of criteria, to solve a given problem (Elske Ammenwerth et al., 2003). It is challenging evaluating software in health. The complexity and difficulty lie in the challenges faced at the intersection of three areas all well-known for their complexity (Hamid & Sarmad, 2010): healthcare services, information systems, and evaluation methodologies. Table 1 sums up the challenges encountered at the intersection of healthcare services, information systems and evaluation methodologies (Alalwany, 2010).

Ammenwerth *et al.* (2003) identify the typical problems in evaluation of IT in health care considering the complexity of the evaluation object, the evaluation project, and the motivation to perform evaluation.

E-health evaluation involved many stakeholders, the most important of them being the users (Gustafson & Wyatt, 2004). Therefore, assessing e-health from the users' perspective should address all the key factors that influence the users' acceptance of the new adopted technologies including the risks and benefits associated with the design and implementation of the e-health initiative in specific contexts. Two types of users, direct and indirect users, may be distinguished. In the first

domain, patients that use e-health applications and health care professionals that use healthcare software will be considered. In the second domain, indirect users are the patients that do not use directly the applications but are indirectly affected by the use of the systems in, among other examples, hospitals, home healthcare, or health centers. Therefore, it is important direct and indirect evaluations, which is why the next section will focus on the evaluation, dimensions to evaluate and tools and techniques.

EVALUTION, DIMENSIONS, TOOLS AND APPROACHES

Evaluation can occur at different phases of a software project: prior to the implementation of the e-health software, during and after the implementation. When evaluate at the pré-implementation, the main reason stands for maintain accountability for expenditure of resources and/or evaluation for decision-making. At the implementation, the rationale for doing evaluation is to assess the user's reaction to system or service and/or evaluation for decision making. Finally, at the post implementation, the intention is for performance evaluation and/or the impact evaluation to assess the overall social and technical impact of the system on users and organizations and/or usability and acceptability evaluations. Alawany (2010) proposes an evaluation roadmap for e-health evaluation with the main elements: 1) the rationale of e-health evaluation; 2) the time frames of evaluation; 3) the stakeholders; 4) the criteria; 5) the methods of e-health evaluation; 6) dealing with the ethical issues; 7) determination of how to interpret and present the evaluation outcomes.

Taking into consideration the current state of knowledge on this question, assessment by the users, either patients or healthcare professionals, occurs at a post implementation level. Hence, the focus of the present article is to focus on the post-implementation evaluation of the satisfaction of the patients and health professionals. It is

therefore essential to determine which dimensions are evaluated and what instruments are used.

What Really Matters for Patients?

What really matters for patients is the starting point in order to determine what should be evaluate when considering a software evaluation. One can consider the perspective from either the tele-healthcare, the software engineering or the healthcare institutions. The analysis of these perspectives may help to understand what must be performed by software in order to meet, or even increase, patients' satisfaction, either directly or indirectly.

Regarding the patients' satisfaction (Williams, May, & Esmail, 2001), the aspects of satisfaction measured by existing studies in tele-healthcare are: 1) professional-patient interaction; 2) patient's experience/feeling; 3) overall satisfaction; 4) technical aspects; 5) preferences for telemedicine or face-to-face consultation; 6) convenience; 7) administrative aspects; and 8) physical environment.

From the software engineering perspective, the approaches to measure the usability of a software using questionnaires as the Computer System Usability Questionnaire (CSUQ) and the Post-Study System Usability Questionnaire (PSSUQ) (Lewis, 1995) the aspects measured are: 1) the overall system usability (OVERALL); 2) the system usability (SYSUSE); 3) the quality of the information (INFOQUAL); 4) the quality of the interface (INTERQUAL).

Existing instruments to measure patients' satisfaction at healthcare institutions such as the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) (National Quality Forum, 2013) or the Patient Satisfaction Questionnaire Short Form (PSQ-18) (Marshall & Hays, 1994) use both similar and different dimensions. The Centers for Medicare & Medicaid Services (CMS), along with the Agency for Healthcare Research and Quality (AHRQ), developed the HCAHPS Survey, also known as Hospital CAHPS®, to provide a standardized survey

Table 2. Scotland's Patient Experience Programme: Patient Priorities for Inpatient Care ((Reeves & Bruster, 2009), from 2,213 patients)

10 Most Important Items	10 Least Important Items
• A clean ward • Staff cleaning their hands before touching patients • Being treated quickly in an emergency • Getting the best treatment for my condition • Doctors knowing enough about my condition and treatment • Clear explanations about what will happen during an operation or procedure • Being told the risks and benefits of any treatment in a way I can understand • Clear explanations of my condition or treatment • Being treated with dignity and respect • Being told how my operation or procedure has gone in a way I can understand	• Being given help to eat my meals when I need it • Being given accurate information about ward routines • Not having to wait around in hospital once I have been told I can go home • Being given help to arrange transport home • Having a choice about which hospital I go to • Not having to pay too much to make phone calls • My religious beliefs being respected • Being able to watch television without having to pay for it • Being able to get an interpreter • Having access to food when I am hungry (not just at mealtimes)

instrument and data collection methodology for measuring patients' perspectives on hospital care. HCAHPS has composite measures, individual items, and global items. Composite measures are communication with nurses, communication with doctors, responsiveness of hospital staff, pain management, communication about medicines, discharge information, and care transition. Individual items concern the cleanliness and the quietness of hospital environment. Finally, global items relate with the overall hospital rating and whether the patient would recommend the hospital. PSQ-18, in its turn, presents separate scores for each of seven different subscales: 1) general satisfaction; 2) technical quality; 3) interpersonal manner; 4) communication; 5) financial aspects; 6) time spent with doctor; 7) and accessibility and convenience.

Cornwell & Robert (2011) in the study of "*What matters to patients'?*", found consistency both across conditions and in relation to the various sectors. Generic themes were:

- Good information provision;
- Having confidence in health professionals;
- Awareness and understanding of specific health condition;
- The right treatment from the right staff at the right time;

- Continuity of care;
- Being treated as a person;
- Partnership with professionals.

Table 2 lists the ten most and least important items for the patients identified Scotland's survey. The findings of the survey broadly support the argument that a generic framework of 'what matters' to patients could be applied across conditions and sectors.

Main Approaches Used for Patients' Satisfaction Assessment

Knowing the key dimensions of patients' satisfaction, as well as the methods used for their assessment, is of great importance.

Regarding e-health (Williams et al., 2001) the majority of studies are descriptive, regarding one service only, some comparing telemedicine services with standard healthcare using the same sample of patients. Only 20% of the studies included an independent control group against which telemedicine was compared. The research was mainly quantitative, with some studies including at least some qualitative component. Tables 3 sums up the methods used for the assessment from the perspective of the healthcare organizations.

Table 3. Methods including tools/surveys for the assessment of patients' satisfaction. Adapted from (Williams et al., 2001).

Author, year	Methods (incl. Tools/Surveys)
(Boyd, 2007)	• Postal questionnaire consisting of 82 statements using a 5-point scale. 54 of the statements were based on core items from the 2006 inpatient survey, 12 from the question bank for the inpatient surveys and 16 were created at the request of the DH. • Cognitive interviews with 8 ethnically diverse volunteers with recent experience of inpatient stays in England were conducted to test the questionnaire.
(Bridges, Flatley, & Meyer, 2010)	• Systematic review of worldwide grey and published literature written in English between January 1999 and June 2008 identified from databases: CINAHL, Medline, British Nursing Index, EMBASE Psychiatry, International Bibliography of the Social Sciences, PsychINFO, and AgeInfo. • 42 primary studies and 1 systematic review met the inclusion criteria.
(Coulter, 2006)	• Expert opinion
(Davies, 2005)	• Qualitative interviews with senior health professionals and managers and a review of the literature
(The NHS Confederation, 2010)	• Seven organisational case studies

Assess Health Care Professional Satisfaction

Doctors and nurses are the main users of software health applications. Studies consider these users as software users but don't measure the possible relation between the use of the applications and the impact on job satisfaction. The only existing job satisfaction scale specifically aimed at community nurses defined was Ellenbecker's Home Healthcare Nurses' Job Satisfaction (HHNJS) scale. The 2001 edition was composed of eight subscales (21 items, 5-point Likert scale): general feeling of overall job satisfaction, interaction, stress, professionalism, task requirements, autonomy, organizational policy and quality of care delivered. Nine subscales were presented in the 2005 (Ellenbecker & Byleckie, 2005) edition (32 items, 5-point Likert scale): autonomy/independence, professional growth, group cohesion/peers, group cohesion/physician, characteristics of the organization, stress/work load, autonomy/flexibility in work scheduling, autonomy/control of work activities and salary/benefits/perception of opportunities elsewhere. So far, no scale to assess doctors' professional satisfaction has been known.

Users' Acceptance

According to (Ullah, Fiedler, & Wac, 2012), the most important determinants for successful e-health implementations are shown in Table 4. As can be seen, user acceptance is the most important factor for any healthcare service implementation

Technology acceptance model was designed to be used in the context of Information Systems for the purpose of predicting information technology acceptance and usage in the work environment. The final conceptualization of TAM model (Davis, 1989) includes two core constructs which are defined as follows: 1) perceived usefulness, i.e., "the

Table 4. Determinants for successful e-Health implementation (Ullah et al., 2012)

Determinants	Influence in Implementation (%)
User acceptance	37%
Technology deployment factors	29%
Leaving behind the organization	13%
Policy and Legislation	11%
Financing factors	10%

degree to which a person believes that using a particular system would enhance his or her job performance”, 2) perceived ease of use: “the degree to which a person believes that using a particular system would be free of effort”. TAM therefore identifies two factors: the perceived ease of use (PEOU) and perceived usefulness (PU) that determine individuals’ attitude (ATT), which influences individuals’ behavioural intention. The Technology Acceptance Model (TAM) is one technology acceptance theory that can be used to understand perceived barriers and benefits of using technology in health care settings. TAM can help predict acceptance of health information technology among users. The systematic review by Holden & Karsh (2010) shows over twenty studies that applied TAM to health care settings by presenting the views of physicians and non-physicians, among which nurses, pharmacists, and patients. The study found that TAM can forecast accurately the portion of Health IT users that are accepting the system. In 2000, Venkatesh and Davis (Venkatesh & Davis, 2000) developed TAM2 in order to capture the social influence (SN) that influences individuals to positively or negatively accept such IT. In 2003, Venkatesh et al. formulated a new model called the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh, Morris, Davis, & Davis, 2003) that was extended in 2012 to UTAUT2 (Venkatesh, Viswanath and Thong, James Y. L. and Xu, 2012). UTAUT introduces three constructs, which are the main determinants of intention to use an information technology. These are defined as performance expectancy, effort expectancy and social influence. UTAUT2 incorporates three constructs into UTAUT: hedonic motivation, price value, and habit. Compared to UTAUT, the extensions proposed in UTAUT2 produced a substantial improvement in the variance explained in behavioral intention and technology use.

Existing Studies to Assess the Impact of Software in the Patients and Healthcare Professionals

H

A nursing record system is the record of care planned and/or given to individual patients/clients by qualified nurses or other caregivers under the direction of a qualified nurse (Currell & Urquhart, 2003). The goal of the study was to assess the effects of nursing record systems on nursing practice and patient outcomes. Eight trials involving 1497 people were included. In three studies of client held records, there were no overall positive or negative effects, although some administrative benefits through fewer missing notes were suggested. A paediatric pain management sheet study showed a positive effect on the children’s pain intensity. A computerised nursing care planning study showed a negative effect on documented nursing care planning, although two other computerised nursing information studies showed an increase in recording but no change in patient outcomes. Care planning took longer with these computerised systems, but the numbers of patients and nurses included in these studies was small. A controlled before-and-after study of two paper nursing record systems showed improvement in meeting documentation standards. No evidence was found of effects on practice attributable to changes in record systems. The number of studies on this topic, albeit of poor methodological quality, indicates that this is an important area of concern for nursing practice (Currell & Urquhart, 2003). However, none of the studies produced results that could be interpreted as evidence of a change in practice that resulted from a change of record system. The studies indicate that nurses believe that there is a link between their clinical practice and the nursing record, beyond its obvious use as a note keeping system. The client held records studies suggest altered and improved relationships between clients and health professionals, and the pain management study sought to demonstrate a direct effect on patient care.

Currell, Urquhart, Wainwright, & Lewis (2010) developed a study to assess the effects of telemedicine as an alternative to face-to-face patient care. Establishing systems for patient care using telecommunications technologies is feasible, but there is little evidence of clinical benefits. The studies provided variable and inconclusive results for other outcomes such as psychological measures, and no analyzable data about the cost effectiveness of telemedicine systems. The review demonstrates the need for further research and the fact that it is feasible to carry out randomized trials of telemedicine applications. Policy makers should be cautious about recommending increased use and investment in unevaluated technologies.

Sinha & Shetty (2015) show the relevance of the attitude of users, namely doctors, in the impact of health information technology. Health information technology (HIT) equips healthcare professionals with the required information and tools for making quality decisions in patient care, but it is always advisable to assess their attitude before its actual implementation. A cross-sectional survey was carried out among 140 doctors of an Ayurvedic center of Southern India. A validated questionnaire consisting of 18 questions based on a 5-point Likert scale was administered to the participants after receiving their due consent. About 75–80% of the respondents concurred that the HIT application, such as electronic health record, has the potentials to reduce the duplication of documentation work, is easy and has an instant processing and real-time access to patient information. They also felt the need of such application to report the patient data to local and national health institutions. A total of 85% of them mentioned that these applications can make the collection and accessibility of patient data much easier compared with paper-based records, whereas 87.4% of them claimed telemedicine as a platform for multidisciplinary collaborative research and patient care. Even though most of the respondents agreed about the role of HIT in improving the quality of health

care, there were many who held no opinion about HIT, including privacy and security of patient data. The need of proper awareness and training program is identified to make them aware about the HIT and its application in patient care, education and research.

Main Approaches Used for Professionals' Satisfaction Assessment

The types of study designs are (Currell & Urquhart, 2003) (Williams et al., 2001) (E Ammenwerth & Keizer, 2005; E. Ammenwerth et al., 2004; Brender et al., 2013): 1) randomized controlled trials; 2) controlled clinical trials; 3) interrupted time series analyses; 4) and controlled before and after studies.

Issues, Controversies, Problems

Studies indicate that many of the main barriers to healthcare information systems (specifically referencing electronic health records) are not technical, but other issues including stakeholder issues such as risk tolerance, physicians' resistance related to time concerns, fears about privacy, the number of sellers vendors on the marketplace and their transience (Walker et al., 2005). Each of the aforementioned barriers is rooted in the associated vested issues in health technologies held by stakeholders. Stahl and Shaw (2011) indicate that success with health information systems needs to bring together various stakeholders and their work practices. Ultimately, Patient Centered Care (PCC) success is determined by the quality of the interactions between patients and clinicians (Epstein, Fiscella, Lesser, & Stange, 2010). A fundamental objective of the PCC model is therefore to integrate information technology applications and infrastructures in every link of the care chain in the belief that Web portals, shared patient records, electronic consultation systems, and online data access for patients facilitate relationships between

professionals and patients by providing sufficient information, patient engagement and mutual feedback (Vikkelsø, 2010). In this context, assessing the impact of the e-health software in patients and healthcare professionals is critical. Despite a large amount of published evaluation studies, many authors report problems during evaluation, such as (E Ammenwerth & Keizer, 2005):

- Unclear, conflicting or changing evaluation goals during the study;
- Large efforts needed for the preparation and execution of the study;
- Complex and sometimes contradictory results;
- Dependence of the evaluation results on the motivation and expectation of the users;
- Uncertainty as to whether results can be generalized to other environments.

Reviews of patient satisfaction research in health care highlight several methodological problems (Williams et al., 2001), including the use of short quantitative questionnaires, lack of standardization, and confounding due to a range of social psychological biases, including self-selection bias, social desirability response bias, and acquiescent replies. Answers to patient satisfaction surveys conducted at healthcare delivery sites are undoubtedly influenced to some degree by the patient's concerns about the impact that any negative feedback may have on the services that are available to them. The results of patient satisfaction studies are often influenced by the method of data collection. Other factors that influenced patient satisfaction included the choice of response format for rating satisfaction, order of placement of satisfaction items within the overall questionnaire, and the distinction between open-ended and closed or dichotomous questions. These findings suggest that "patient satisfaction" is influenced, at least in part, by the nature of the methodology used to measure it.

SOLUTIONS AND RECOMMENDATIONS

H

E-health software satisfaction assessment is difficult, time consuming and resource demanding. Existing approaches are designed for a very specific scenario, so the existing results are difficult to generalize and do not allow a comparison between software applications. One possible solution is the development of a global validated tool and method for each sectorial health service allowing in this way the benchmarking of the applications. A validated instrument and their application method leading to a unique scale of satisfaction impact assessment could be used in decision-making and impact estimation of a commercial e-health product, the development of new products, and as the backbone of regulatory work. Finally, as stated in this work, these instruments must encompass a holistic approach for measuring the satisfaction either of the patients or of the healthcare professionals.

FUTURE RESEARCH DIRECTIONS

Due to the importance of the evaluation of the software from the perspective of patients and healthcare professionals many fruitful research directions exist and the academic and non-academic community is invited to develop efforts for contributions in the field. This work shows the need to develop standard and holistic tools and methods to perform this assessment at least at the health service level. It also, shows the need of tools and methods easy and faster to apply. The heavy investments in e-health request the existence of an impact scale in the patients and professionals that would allow the comparison between software applications. Moreover, the presented studies are time consumer, requiring a lot of availability either of the research teams either of the patients and health professionals. The existing instruments neither take into account many dimensions of

patients' satisfaction nor consider jobs satisfaction in its equation. Finally, there's a lack of tools and methods to perform satisfaction assessment prior to the implementation of the e-health software and during the implementation.

CONCLUSION

The paper provides a thorough discussion about the relevance of the evaluation of the software from the perspective of the patient and healthcare professionals. It holistically presents the concept of satisfaction of the patients and the professionals, with dimensions and methods both measured. It demonstrates the need to develop new efforts in this research area due to the existing fragilities. The paper may be a helpful tool for those who need a solid support from where to start or to continue their work.

KEY TERMS AND DEFINITIONS

e-Health: According to the World Health Organization (World Health Organization, n.d.), e-health is: “*the transfer of health resources and health care by electronic means. It encompasses three main areas: 1) the delivery of health information, for health professionals and health consumers, through the Internet and telecommunications; 2) the use of the power the power of IT and e-commerce to improve public health services, e.g. through the education and training of health workers; 3) the use of e-commerce and e-business practices in health systems management*”.

Hospital Consumer Assessment of Health-care Providers and Systems (HCAHPS): A standardized survey instrument and data collection methodology for measuring patients’ perspectives on hospital care. The HCAHPS survey contains 21 patient perspectives on care and patient rating items that encompass nine key topics: communication with doctors, communication with nurses, responsiveness of hospital staff, pain management, communication about medicines, discharge information, cleanliness of the hospital environment, quietness of the hospital environment, and transition of care. The survey also includes four screener questions and seven demographic items, which are used for adjusting the mix of patients across hospitals and for analytical purposes. The survey is 32 questions in length (National Quality Forum, 2013).

Organizational Commitment: Organizational commitment refers to the extent to which the employees of an organization see themselves as belonging to the organization (or parts of it) and feel attached to it (Meyer, Kam, Goldenberg, & Bremner, 2013)(van Dick & Ullrich, 2013).

Patient Satisfaction Questionnaire Short Form (PSQ-18): PSQ-18, Likert scale questionnaire proposes seven dimensions of patient satisfaction directed toward their healthcare professionals. These are 1) general satisfaction, 2) technical quality, 3) interpersonal manner, 4) communication, 5) financial aspects, 6) time spent with doctor, and 7) accessibility and convenience. Each domain is tested through different related questions, which is of substantial benefit when one aims to identify a particular area to improve on. The general satisfaction has strong correlation with the other domains and thus it is important to improve in all (Marshall & Hays, 1994).

Software Quality: The “*capability of software product to satisfy stated and implied needs under specified conditions*” (“ISO/IEC 25010:2011 Systems and software engineering -- Systems and software Quality Requirements and Evaluation (SQuaRE) -- System and software quality models,” 2011) and as “*the degree to which a software product meets established requirements; however, quality depends upon the degree to which those established requirements accurately represent stakeholder needs, wants, and expectations*” (IEEE P730™/D8 Draft Standard for Software Quality Assurance Processes, 2012).

Usability: Usability relates with the concept of ease of use and the ability to use a product for its intended purpose (Bevan, 1995).

User Acceptance: For technology to improve productivity in organizations first users’ must accept the technology and use it. Models explaining the factors and predicting user intention for using technology are of great importance for health information systems development (Venkatesh et al., 2003).

Technology Design and Routes for Tool Appropriation in Medical Practices

Paola Figuerola
Cinvestav-IPN, Mexico

INTRODUCTION

Nowadays it is recognized that the developments and use of digital technologies are changing the way in which people communicate, get access to a variety of information, solve problems, and discuss solutions. These technologies open up novel avenues for people to share practical and specialized knowledge from a variety of domains, and interest or goals. Tools can be physical or virtual artifacts and they influence human cognition and act as mediators between the phenomenological and conceptual world (Santos-Trigo, et al. 2016). In health areas, experts or professionals such as physicians, nurses or physiotherapists rely on social media (YouTube channels, blogs, wikis, or specialized webs) to share knowledge and practical experiences. Similarly, patients look for information on diseases and health advice and they often interact, via Internet, with experts to monitor their health and to interpret lab results. An important feature of the Web or an online platform is that it allows the participation of experts and users with a variety of experience or knowledge to build a source of accumulated knowledge in constant scrutiny. Denecke (2015) identifies three main groups as users of medical social media with different aims and purposes: patients, healthcare professionals and researchers. Thus, through the medical web, patients interact with health professionals and other patients to get

information on diseases, treatments, prevention or ways for operating tools for diseases. Healthcare professionals interact with other colleagues and patients to discuss latest results or to identify and share experiences and best practices. Researchers interact with other researchers to discuss treatment results and information on treatment outcomes and information of disease development and progression. How is a medical web system constructed? What criteria are used to select the information to be included in the online system? ¿How do patients process and use the information they consult? Available medical data in online platforms might vary and increase in volume and themes, then data visualization becomes important for physicians and patients to overview and interpret changes in health status. Likewise, physical tools designed by engineers and other professionals (magnetic resonance imaging, catheters, etc.) are also transforming medical practices such as surgeries and disease detection and treatments. Thus, it is important to analyze the extent to which users of both physical and virtual artifacts get engaged in activities to transform those artifacts into an instrument to solve problems. To this end, we focus on the importance for users to develop cognitive schemata that shape their appropriation of the tool affordances in problem solving environments (Santos-Trigo, et al, 2015).

The design and use of technological artifacts in medical practices involve the participation of

several experts' communities including engineers, scientists, and medical doctors. Thus, to delve into what happens to artifacts (designed by engineers) when they enter into medical practices implies not only to uncover what engineering and medical practices entail, but also to address how both agendas could converge or incorporate common goals. Regarding the engineering as a discipline, the National Research Council (NRC) (2009) pointed out its problem solving approach to design and create human-made products under certain conditions or constraints. Some of those constraints involve taking into account principles that encompass science and scientific laws, budget restrictions, available materials, sustainability, ergonomics, and ethical issues.

Progress in science and engineering goes hand in hand, science advances often depend on tools developed by engineers and reciprocally scientific knowledge guides and permeates engineering designs. Nowadays, it is not unusual to find engineers working with medical doctors and researchers in the design of artifacts that aim to improve human health.

Engineering design is a purposeful activity bound by specifications and constraints and an eminently collaborative enterprise. It involves an interactive process in which the design is tested and modified and it often offers several solutions to a particular problem (NRC, 2009). In general, the design and the construction of artifacts are tasks that require an expertise in science of materials, control, ergonomics and biomedicine. And there is set of standards that any medical artifact needs to fulfill in order to be used within the medical community. However, as Béguin (2003) pointed out the design of artifacts does not finish when the tool or object fulfills material and technical requirements; it should include how users transform the artifact into an instrument. Then, how does the medical community develop the needed expertise to use those artifacts efficiently in medical practice? This question becomes important to identify and delve into a research area that examines ways in which medical doctors transform

and artifact (physical device) into an instrument to solve problems. Then, what information and actions are important to characterize the process to transform an artifact into an instrument? Hadolt, Hörbst & Müller-Rockstroh (2012) cited a four-phase model (Hahn, 2004) that includes appropriation, objectification, incorporation, and conversion activities. The authors stress that the incorporation of artifacts into practices depends on social, cultural, and economic conditions.

It is important to analyze the extent to which medical doctors construct cognitive schemata that explain what we called their appropriation process of an artifact. In this process, it is recognized that tools shape and are shaped by the users' actions. Trouche (2004) pointed out the importance of considering the instrument as an extension of the body that becomes an organ formed by the artifact itself and by a psychological part that helps the user to mobilize the artifact to carry out activities and solve problems. Béguin (2003) emphasizes the difference between an artifact and an instrument or a problem-solving tool. The latter is made up by the artifact and the user's social and private cognitive schemata. The artifact characteristics that include ergonomics and constraints and the cognitive schemata developed by the user during the activities are important for the transformation of the artifact into a problem-solving tool or instrument to solve problems.

Artigue (2002) pointed out that users need to get involved in an appropriation process to transform an artifact or physical device into an instrument for specific use. This process leads users to gradually construct personal schemata or to appropriate pre-existing social schemata to appreciate its potentialities and use them in problem solving situations. Thus, relations between users and objects are shaped by ways in which a community of practice acts in problem solving environments. Trouche (2004) also mentioned that the development of the user's psychological component could be categorized in terms of three related functions: A *pragmatic* function where the subject achieves a particular goal, a *heuristic* func-

tion in which the subject visualizes and pursues an action plan; and an *epistemic* function where the subject comprehends and makes sense of what is being achieved.

BACKGROUND AND RATIONALE

Delving into the ways that medical doctors develop an expertise in the use of artifacts in their practice implies examining not only what activities they engaged in order to develop such expertise; but also reflecting on common issues that permeate or characterize two fields: the engineering design and medical practice. In this context, we stress the interdependence between scientific principles that support the design of tools and those activities involved in using those tools in problem solving environments.

Throughout the chapter, it is recognized that performances and advances of humankind go hand in hand with developments and use of technology. Thus, the use of tools not only influence cultural and science developments (Trouche, 2004); but also some tools facilitate the maintenance of physical wellness and humans comfort. Koszalka et al. (2014) pointed out that the use of technology goes beyond developing an expertise in its practice, it also includes that subjects develop a set of abilities for accessing relevant medical information, constructing an effective communication among colleagues and patients, and supporting the subjects participation in virtual practices environments. Thus, the use of tools has been shaping the developments and practices in medicine and in all disciplines. As a consequence, tasks in the design field and ways in which users appropriate the tools become relevant not only to incorporate the tools in different practicing domains, but also to provide feedback to improve the tools design.

Are there common principles that characterize the design and development of particular tools? How do engineers design artifacts? How are designed technologies or tools used in medical practices? To what extent does the design process

influence or shape ways in which medical doctors use the tool in their practices? The discussion of these questions provides basis to comprehend and frame ways in which medical doctors develop an expertise in the use of the tools. In a broader context, the relation between science and technology is a theme that should be examined from diverse angles or perspectives. In terms of goals and methods, engineering design, as an area of study, can be compared with processes involved in scientific developments, both processes rely on or are conceptualized as problem solving approaches (Santos-Trigo, 2010).

Trouche (2004) pointed out there are cultural biases or differences between Western and Eastern cultures regarding the value of physical and manual work vs. cognitive or intellectual work. While Eastern cultures recognize a dialectic interaction between mind and body, the West tends to privilege intellectual or mind activities over physical or manual activities. Recently, science and technology communities recognize that scientific inquiry or science development, technology, engineering, and mathematics are fields in constant interaction and play an important role in society developments. Trouche cites a Francis Bacon' passage that seems to recognize the importance of both intellectual and manual activities: "Human hand and intelligence, alone, are powerless: what gives them power are tools and assistants provided by culture" (p. 283). That is, both science and engineering or technology activities are fields that depend on each other and as a consequence, multidisciplinary approaches that incorporate principles and methods from several realms seem essential to identify, frame, and solve society problems. In particular, information regarding how scientific and technology developments influence not only the building of disciplinary knowledge or practices; but also the users' appropriation process of those developments becomes an important component of the academic agenda. Similarly, Ritella and Hakkarainen (2012) pointed out that in order to fully understand the role of artifacts in disciplinary practices, it is important to think

of them as cognitive prostheses that enhance and expand human creativity and ways to solve practical problems.

DESIGN AND USERS CHALLENGES

Béguin (2003) underlines that the design of an artifact, factory, or a vehicle is both an individual and collective process based on two principles: a) *differentiation* in which tasks involved in the design are distributed among the team members and b) *interdependence* that recognizes the need to ask for the participation of several specialists to work on a product or artifact. Likewise, the NRC (2009) states that engineering design demands that engineers work in collaboration with teams and clients. That is, the design process can be conceptualized as an ongoing activity in which the designers' plans and knowledge are key to achieve the task; but also during the same process some unexpected goals and challenges need to be attended or addressed. Indeed, although there is no formula to characterize the interactive process involved in engineering design, it is accepted that one initial step is the identification of a problem that eventually needs to be explicitly formulated. This problem becomes a platform to generate ideas and actions to solve it. Next, is the evaluation of potential solutions in which models and prototypes are constructed and evaluated in terms of the extent to which the solutions meet standards and constraints; an optimization process. A salient feature of engineering design activities is that goals and actions take place within a set of specifications and constraints and involve the consideration of multiple solutions. Thus, important steps that characterize the engineering tasks design include: the identification of the problem and objectives, the definition of goals and constraints, the search and gathering of key information, the identification of possible design solutions, contrasting and analyzing the pertinence of solutions, building and implementing the design, testing and evaluating such design and repeating all steps as necessary (NRC, 2009, p. 83).

It is observed that the aforementioned design process steps do not include, at least explicitly, the importance of taking into account the appropriation process in which users engage in order to use "efficiently" the product generated by the design. Thus, the challenge of communities involved in artifact designs is to extend the design process to include information regarding the subject's appropriation process of the artifact. That is, the interactive cycle that characterizes the process of designing artifacts should also include information regarding how the artifact becomes a tool for the client or user. In addition, feedback provided by users to designers plays an important role in improving and designing new artifacts. In the appropriation process of artifacts, the analysis of experts' behaviors and actions shown through dialogue-conducting strategies play a crucial role for subjects to transform an artifact into an instrument to solve problems (Folcher, 2003).

SCOPE OF THE ARTICLE: A FOCUS ON ARTIFACT APPROPRIATION

The analysis of the process involved in the subjects' appropriation of tools requires the documenting of ways in which a community of practices (Perkins, 2009) behaves in problem solving environments. In this context, it becomes important to analyze and document group or subjects' interactions within a community formed by expert such as cardiologists, mechanical and biomedical engineers, technicians, and nurses during the process of transforming a particular artifact into a problem-solving tool. The user's tool appropriation in medical practice often takes place within a community of practice formed by experts and specialists including anesthesiologists, nurses, medical experts, technicians, etc. where novices doctors participate gradually in several activities that involve the coordination of physical skills required while inserting of a catheter or stent and the corresponding interpretation information available through monitor displays.

There are different frameworks to delve into the subjects' appropriation process of particular tool; however, recently a *bricolage* perspective that involves relying on more than one framework has been used to explain how a particular community develops knowledge and expertise in problem solving activities. For example, the construct *community of practice* was originally developed as a learning theory that fosters self-empowerment and professional development and it has evolved to become a framework for improving organization's competitiveness (Li, et al. 2009). In this context, a community of practice framework can be extended to explicitly take into account theoretical constructs used in cognition and artifact studies (Verillon & Rabardel, 1995). These studies explicitly recognize and address the importance for subjects to transform a technological artifact into a problem-solving tool. Key in this approach is the recognition that the subject's appropriation of tools for problem solving activities involves an adaption and transformation of the artifact known as an instrumentation process and the development of cognitive schemata or instrumentalization process. Those schemata are explained in terms of subjects' cognitive systems associated with the use of artifacts (Rabardel, 1995). Ritella and Hakkarainen (2012) relied on these two concepts, instrumentation and instrumentalization to explain a dialectic relationship or mutual shaping between people and tools during the appropriation process. Cognitive behaviors are expressed by subjects' use of language and explicit use of strategies to coordinate information provided during the use of the tool. In addition, the artifact appropriation process takes place through subjects' legitimate peripheral participation in an ongoing social practice. Lave (1991) recognizes that an active participation as member of a community of practice shapes new members' identities and help them internalize community values and actions. Thus, as a part of a community of practice the subject develop and internalize knowledge to become a member of that community.

SOLUTIONS, RESULTS, AND REFLECTION

Currently, many research projects emphasize the importance of formulating and approaching scientific and technological problems through the convergence and collaboration of multiple disciplines. For example, Stewart (2011) introduces what he calls the sixth revolution in biology, the first five include: the microscope, classification of living creatures, the theory of evolution, the discovery of the gene, and the structure of DNA, in which he proposes to wide the scope of ways of thinking of the discipline to include mathematical approaches as the sixth revolution to frame and work on biological problems. "Mathematics provides a new point of view, addressing not just the ingredients for life, but the processes that use those ingredients" (p. 18). Similarly, a task of designing artifacts requires the participation of experts to develop both the technical and ergonomic components, but also to incorporate information regarding how an artifact is used in actual practices. Recently, in the USA there is an increasing interest for medical school reform that includes the use of technologies to help enhance and standardize the medical curriculum. For instance, scholars in medical educations recognize the importance to carry out multi and interdisciplinary studies to analyze ways to incorporate educational technologies in medical curricula (Koszalka, Epling, and Reece-Barnes, 2014). In particular, it becomes relevant to characterize medical doctors' cognitive and metacognitive behaviors that appear during their processes of appropriation of technological tools. That characterization includes the subject's development of schemata, mental models, and a language to communicate and eventually carry out the community's goal. Figuerola (2014) reviewed different studies that focused on individual's tools appropriation in several fields including the use of digital tools in mathematical practices. In addition, she examined medical practices involving the use several artifacts to introduce catheters or

stents where newcomers' doctors were guided to develop an expertise in those practices. In her analysis, she found that during the subjects' appropriation process of artifacts there are goals to meet at different stages that are monitored within the community. The stages involve initial recognition of a community, direct involvement in particular actions or routine activities, and the management of time to carry out and regulate the development of the activities (Dousay, Igoche and Branch, 2014). Thus, research results consistently show that there are three crucial phases to distinguish the subject processes to develop an expertise in the use of artifacts.

Initial familiarization within the community's goals and carrying out peripheral activities. At this stage, the medical doctor, who is developing an expertise to use a tool, gets engaged into a set of routine tasks that includes checking proper disposition of the surgery equipment, functioning of the auxiliary equipment and in general terms he/she observes the role played by each team member during the entire process of using a particular tool (catheter, for instance). In addition, the subject carries out pragmatic and routine tasks to help other team members and listen to others and to observe actions that medical expert exhibit during the entire process of using the tool. It is important to mention that the expert continuously calls the attention of the team members to pinpoint critical events that occur during the use of the tool. At this stage, they develop cognitive skills to initially visualize the complexity involved in using the tool to carry out some particular tasks and recognize the need to work and interact with others (Lavigne and Mouza, 2013).

Gradual use of the tool. At this stage, the subject is gradually asked to participate into a series of tasks that includes the actual use of the artifact, in particular stages of the surgery involving the initial introduction of a catheter or stent and moving the artifact to detect a particular spot that needs attention. In general terms, the subject begins to develop and show a heuristic approach to take decisions that define and anticipate actions

related to the use of the device. For example, it is evident that in this phase, that even when the subject receives some explicit guidance to carry out particular tasks, the expert scaffolding activities to direct such guidance eventually get reduced or faded. Van Merriënboer, and de Bruin (2014) emphasize that people develop an expertise or learn something by being engaged directly in activities of doing, exploring, observing others, solving problems, analyzing information, repeating, etc. Subjects not only gradually get involved in tasks but it is evident the complexity of the tasks they participate increase gradually within the community.

Full participation that involves the subject's response to new events that appear during the actual use of the tool. In this phase, there is evidence that the subject has developed strategies and skills that help him/her to not only carry out all procedures to use the main artifact and auxiliary instruments; but also he/she exhibit a full coordination of emerging information displayed during the intervention process. That is, at this stage, the expert role is reduced to basically monitor the subject behavior and actions. It is important to observe that in addition to the subject full control of the process of using the tool, the subject shows a clear physical coordination between his/her hand and the manipulation of the artifact. That is, the artifact becomes an extension of his/her hand. Hahn (2004) mentions that as a result of an appropriation, understood this as the process by which objects change (not materially), the object or artifact is no longer what it used to be; but it becomes an extension of the subject's body and cognition.

Figuerola (2014) asked 52 practicing physicians working on different areas in public and private institutions about their experiences in the use of several medical artifacts and about how they developed the skills and knowledge to incorporate them in their professional practices. The questionnaire included 9 statements addressing issues regarding the importance of theoretical knowledge and the artifact; the role of observing

Figure 1. Relation between experts and residents in medical practices

experts and gradually being involved in artifact use; the development of a specialized language to understand and explain decisions that emerge during the use of a particular artifact; and effective coordination between visual, hand movement, monitor information and the use of the artifact, and the recognition of patterns involved in actual practice and patient status. Figure 1 and 2 show frequency, percentages, and a bar graph of the answers that the 52 participants gave to two statements.

FUTURE RESEARCH DIRECTIONS

In this contribution we present a research area that deals with the importance of extending the process of designing and producing medical artifacts to include or take into account information regarding the transformation of an artifact into an instrument or problem solving tool. That is, it has been argued that the design of an artifact should not only involve the contribution of experts in several fields addressing technical or material issues; it

Figure 2. The coordination cognitive and body movements

should also include the participation of research groups that explicitly focus on the analysis of what the subjects' process of tool appropriation entails. The initial review provides a rationale to focus on analyzing cognitive behaviors that users exhibit during their appropriation process of the artifact. A challenge that emerges in this perspective is to develop the language and communication strategies to productively interact and communicate among the members of those diverse communities. Schoenfeld (2011) proposes three constructs to explain in detail what problem solvers do on a moment-by-moment basis while engaging in a problem solving process: the problem solver's resources, goals, and orientations. He suggests that these constructs offers practitioners, and problem solvers in different domains tools for reflecting on their practicing decisions. In his book, he uses the constructs to analyse and predict the behaviours of mathematics and science teachers and a medical doctor. It is also important to recognize that artifacts are developed within a cultural context where communities of practices reside and work, then what happens when the artifacts or products are used in environments that not necessarily reflect those cultural values? This could be a research question that designers and practicing communities should frame and pursue. In this context, the analysis of the subjects' appropriation process of the artifact should also include information regarding cultural values and traditions associated with environments where the device will be used. Finally, it is important to examine extant frameworks that are used to analyze ways in which subjects transform an artifact into an instrument and discuss the extent to which a *bricolage* perspective can be used to identify basis to characterize what is common in the subject's process of appropriation of different types of artifacts and what elements depend on the use of a particular device.

CONCLUSION

This contribution provides important information for both medical communities and biomedical engineers to discuss the process and ways to guide novice doctors to fully learn the use of the tool, and to improve the design of the tool. The distinction between an artefact and an instrument or tool is key to comprehend how the subject, a medical doctor in this case, develops knowledge about the artifact itself, its uses to transform such artifact into an instrument or problem solving tool. In particular, it became important to foster a full collaboration between both communities in designing and developing an expertise in using artifacts in medical practices. That is, it becomes important to consider users in the design of an artifact and also to involve them in the process by which users transform the artifact into an instrument. Design-in-use captures the idea that design and use is a continuous process that never ends. In addition, thinking of users' appropriation process of artifacts as an essential component of the artifact design implies to take into account information regarding how that appropriation takes place and could be achieved and monitored. This consideration or integration could be of benefit for both communities, engineering and medical communities, in terms of addressing and solving users' appropriation issues through a continual collaboration.

KEY TERMS AND DEFINITIONS

Artifact: A material or physical object designed to sustain and improve human activities.

Catheter: A medical artifact that is inserted in a patient body to treat a disease or to perform a surgical operation.

Cognitive Scheme: The subject's internalisation of actions to use the tool in practice and to anticipate and respond to emerging actions and to comprehend what the user is doing with the tool.

Community of Practice: A group of people or special interest group involved in activities to promote individual and collective learning. Problem solving activities are key in learning communities.

Engineering Design: A goal oriented activity to create and design human-made products under constraint such as nature and science principles, time, money, sustainability, materials and ergonomics.

Instrument or Tool: An Artifact becomes a tool or an instrument when its user develops cognitive schemata to incorporate them into its social or discipline practices.

Stent: A medical artifact that is inserted into a natural conduit in a patient body to prevent or to treat a disease.

Tool Appropriation: The process by which the user transforms an artifact into an instrument. Thus, the tool or instrument becomes a user's functional organ formed by an artifact and a psychological component.

Trends in Health Care Information Technology and Informatics

INTRODUCTION

It was not until 1994 that the United States (U.S.) health care industry established information systems capable of handling a universal delivery system. These Information Technology Systems (ITS) operated along enterprise and system boundaries in the Health Care Delivery System (HDS). ITS have become fragmented by the proprietary business benefits of large vendors that want to control patient information (Accenture, 2001). Practical tools, especially computers, continue to be created and rapidly placed in industry with the ability of organizations to accept, accommodate, and even embrace technology moving at a varied pace (McHaney, n.d.). The health care industry has been one of the unhurried organizations to embrace the computer revolution in regards to patient care. Health organizations have been using computers for years in business departments. Health care comprises the use and management of a profusion of information that must be collected, managed, reviewed, processed, and mined (McHaney, n.d.). Technology changes rapidly and maintaining the status quo in health care actually means falling behind; and health organizations cannot afford to do that in a technology-driven world (Rutsky, 1999).

The implications facing health organizations are driven by the substantial pressure to implement Health Information Technology (HIT) systems that have “certified” Electronic Health Records (EHRs) applications and that fulfill the federal

government’s definition of “meaningful use” or risk significant financial penalties in the near future (Ford, Menachemi, Huerta, & Yu, 2010). To offset this pressure and cost, every hospital in the U.S. is eligible for a minimum of \$2 million incentive with larger hospitals eligible for more funds to purchase and incorporate EHRs (Bau, 2011). With this in mind, health organizations such as larger hospitals located in urban areas, and teaching hospitals are implementing EHRs at a quicker rate (Jha et al, 2009). In 2014, research found approximately 38 percent possibly eligible hospitals achieved meaningful EHR implementation by the end of 2012 (Diana et al, 2014). The Health Information Technology for Economic and Clinical Health Act (HITECH) of 2009 is driving fundamental market and industry changes that health organizations need to be strategically poised to deal with and implement. This chapter investigated the trends in health care information technology and informatics related to patient care. The chapter will consist of the following sections: background; issues controversies, and problems; solutions and recommendation; and future research directions in health care.

BACKGROUND

Health care expenditures have amplified melodramatically during the past 50 years, mutually in total terms and as a share of Gross Domestic Product (GDP) (Center for Medicare and Medicaid

DOI: 10.4018/978-1-5225-2255-3.ch330

Services [CMS], n.d.). Expenditures in the U.S. health care segment computed over \$2.7 trillion in 2011, increasing from up the \$698.3 billion expended in 1980, increasing by a factor of 3.9. Health care expenditures in 2011 attributed for 17.9 percent of GDP, resulting in doubling of the shares from 1980 (CMS, n.d.). These expenditures have led to Quality Management for Health Care System to make available a structure to aid health organizations in communicating, monitoring, and incessantly advancing the whole HDS (James, n.d.). The vision for the Center for Medicare & Medicaid Services (CMS) Quality Strategy is to optimize health outcomes by leading clinical quality improvement and health system transformation. This has resulted in and gives indication back to the very suggestion that a systematized system to achieve high quality care can be a front-runner to lowering health care costs (James, n.d.).

The Patient Protection and Affordable Care Act (PPACA) entails 10 separate legislative Titles, with more than a few major goals. As it relates to quality, the goal is to increase health-care value, quality, and efficiency, while dropping lavish expenditures and creating the health-care system more accountable to a varied patient population (Rosenbaum, 2011). Also, the Act invests in the development of a multi-payer National Quality Strategy to create multi-payer quality and efficiency procedures to stimulate worth procuring, better safety, and all-embracing health information across public and private insurers (Public Law 111-148, 2010). In the long run, this will build on the HITECH Act, which was ratified into law in 2009 as measure of the American Recovery and Reinvestment Act (ARRA) (Public Law 111-5, 2009).

Trends in Health Care Information Technology and Informatics Issues, Controversies, Problems

Today's digital technology plays a significant role, permitting the storage and rapid retrieval of patient records and other important information. At the same time, patients expect their sensitive per-

sonal information to be handled appropriately, to ensure accuracy and confidentiality (Hall, 2014). Privacy and security is a humongous concern for a hospital's network infrastructure. Implementing security systems to prevent data breaches and leaks, keep Patient Health Information (PHI) secure, and managing the secure transmission of electronic medical record data are all major issues in the industry. Management must continue addressing ethical and legal issues with regard to control of information. In multifaceted health care organizations, management is realizing efficiency goals assist with meeting more intricate goals (Prior, 2006).

Due to the economic crisis of 2008, the American Recovery and Reinvestment Act (ARRA) of 2009 directed nearly \$150 billion in new funds to the health care industry. According to Health care IT News (2015), it included \$87 million for Medicaid, \$24.7 billion to subsidize private health insurance for people who lose or have lost their jobs, \$19.2 billion for health information technology, and \$10 billion for the National Institutes of Health (NIH). Also, the Act provided \$650 million to support prevention and wellness activities targeting obesity, smoking, and other risk factors for chronic diseases. Subsequently, it obligated \$500 million for health professions training programs to include \$300 million for revitalizing the National Health Service Corps (NHSC) (Health care IT News, 2015). This will allow promoting the foundation for performance reporting on a system-wide source so that patients can more readily get information about their own health care and how their health-care providers perform.

ARRA funding was designated to modernize the health care system by promoting and expanding the adoption of HIT. The federal government stated achieving this goal would reduce its health costs by more than \$12 billion over the next 10 years (Sandlot Solutions, 2014). ARRA targeted funds at implementing a national infrastructure for health information technology. ARRA allocates \$19.2 billion to increase the federal coordination of

that effort and the use of electronic health records (Portfolio Media, Inc., 2009). Politicians are still arguing over its efficacy. Opposition continues to state that say the stimulus was too big or too small and the government should have allocated those billions of dollars more prudently (Gura, 2014).

According to Blumenthal (2010), the HITECH Act of 2009 is an attempt to improve the performance of health care systems through the use of technology, such as EHR's. The HITECH Act is focused on health organizations using certified EHRs. The HITECH Act was touted to expand the federal government ability to establish a national electronic patient records system by 2014 (APA Practice Organization, 2014). This allows the Department of Health and Human Services (HHS) to have the authority to institute programs for improving health care quality, safety and efficiency through the advancement of HIT (HealthIT.gov, 2014). The HITECH Act provides for enforcement and penalties for violation of privacy and security standards, including permitting enforcement through state attorneys general (APA Practice Organization, 2014).

Patient implications include reduced cost and better quality of care. The HITECH Act of 2009 supports health care quality improvement and cost reductions. This falls in line with the PPACA. An example is the required functions of EHRs being aligned "to requirements for emerging models of health care delivery improvement, including "patient-centered medical homes," a term for health care providers who emphasize partnerships between patients, their physicians, and Accountable Care Organizations" (Bau, 2011, p 1). The Act has the ability to involve patients and health consumers in their own self-care, even rallying entire communities into more patient self-awareness. In addition, PPACA has come up with a Duals MediPlan, where only some regions and specific states have the luxury to take advantage of these benefits. The Dual-Medi services provide in-home care and other services that Medicare and any other plan will not cover (Senior Quote, 2014).

The PPACA launched the Institute for Comparative Clinical Effectiveness Research to support the type of research essential to identifying the most appropriate and efficient means of delivering health care for diverse patient populations (Public Law 111-148, 2010). All the way through, these ingenuities foster improved quality and materials that underline hard work to accumulate statistics about health and health-care inequalities. This permits the country to enhance measure advancement, for the populace as a total and subpopulations with prominent possibility for reduced health consequences (Rosenbaum, 2011). Quantities of health care assistances are mandated by either federal law, state law, or both. Between the federal government and the states, there are in the neighborhood of 2,000 health insurance mandates (Bihari, 2014).

According to Dingley, Daugherty, Derieg, & Pershing (2008) effective communication among health care professionals is challenging due to a number of interrelated dynamics:

- Health care is difficult and volatile, with professionals from an assortment of disciplines involved in providing care at various times, often dispersed over several locations, creating spatial gaps with limited opportunities for regular synchronous interaction (Zwarenstein & Reeves, 2002).
- Health care providers often have their own disciplinary view of what the patient needs, with each provider arranging the activities in which they act independently (Zwarenstein & Reeves, 2002).
- Health organizations have traditionally had a hierarchical organizational structure, with substantial power distances between physicians and other health care professionals. This commonly leads to a culture of inhibition and restraint in communication, rather than a sense of open, safe communication (psychological safety).

Table 1. Benefits of using information and communication technologies in the health care sector. from Implementation and Integration of Regional Health care Data Networks in the Hellenic National Health Service, by Lampsas, Vidalis, Papanikolaou, & Vagelatos (2002)

Health Care Players	Benefits
Administration Units	• Policy development and decision-making are strongly supported by effective and on-time information gathering and distribution. • Easier adaptation to eEurope challenges. • Supply control; better budget monitoring. • Overall improvement in the way citizens are served.
Hospitals	• Increased efficiency in communication between hospitals, administration units, social security services, careers, physicians, and citizens. • Personnel familiarization with information technologies through Internet-access operations. • Patient-record traffic support. • Reinforcement of the need to build health care information systems (HCISs) and local networks in hospitals. • Utilization of the developed Intranets. • Better information services for the citizens. • Advanced telematics services (i.e. telemedicine applications in difficult-to-reach regions).
Health Care Personnel	• Meets the increased need for telecommunications not only for medical, but also for compensation reasons. • Participation in care chains and relevant coordination. • Physicians' collaboration. • Patients' history data retrieval. • Continuing education services; familiarization with new technologies through special training programs. • Interaction with patients to provide advice or prescriptions.
Citizens	• Use of the Internet for health-related information retrieval. • Information and communication technologies will increase interest in citizens' health-issues management. • Creation of the appropriate infrastructure for future provision of special health services for specific population groups (eg, in-house services for older people or patients with long-lasting attendance and nursing needs).

- Differences in education and training among occupations in the health care field often result in different communication styles and methods that further complicate the scenario and render communications ineffective.
- Teamwork and effective communication are crucial for safe patient care; however, the educational curricula for most health care professions focus primarily on individual technical skills, neglecting teamwork and communication skills.

Table 1 is factors that lead to the requirement to implement health-authorities interconnection infrastructure. Furthermore, these factors may be seen as the targets that are and will be accomplished (Lampsas, Vidalis, Papanikolaou, & Vagelatos, 2002).

SOLUTIONS AND RECOMMENDATIONS

Technology in the form of software and hardware has given the health care industry the opportunity to transform services. Regulations and technologies have given patients control over their care and the autonomy to choose innovative physicians able to deliver personal service. Continuous adherence to government requirements and insurance carrier demands requires software, hardware, and related components to ensure success. Health care organizations need to safeguard patient information with secure storage of all compliance-related documentation. This includes ensuring the ability to control access, add, or modify records from patient information to billing and reconciliation of data. Health Insurance Portability and Accountability Act (HIPA) and ARRA affect the various health care organizations.

Table 2. Economic impact for the U.S. health care industry resulting from Communications Inefficiencies Sector from *The Imprivata Report on the Economic Impact of Inefficient Communications in Health care*, by Ponemon Institute (2014 p. 3).

Workflows	Extrapolated Annual Cost of Inefficient Time per Hospital	Number of Registered Hospitals ²	Extrapolated Annual Impact for the Industry (U.S. \$ Billions)
Patient Admissions	\$727,957	6.409	\$4.67
Emergency Response	\$265,254	6.409	\$1.70
Patient Transfers	\$753,755	6.409	\$4.83
Total	\$1,746,966	6.409	\$11.20

¹United States Bureau of Labor Statistics, Occupational Employment Statistics May 2012.

²American Hospital Association May 2014 Update on the number of registered U.S. hospitals

Prohibiting the disclosure of records without the written consent of the individuals is essential unless one of the twelve disclosure exceptions listed in the Act applies. The Privacy Act of 1974 created the System of Records Notices (SORNs). This moved onto the Privacy Impact Assessments (PIAs), the “E-Government Act of 2002 that required government agencies to assess the impact on privacy for systems that collect personally identifiable information in PIAs” (U.S. Department of Health & Human Services [HHS], n.d., para 6.). Prohibiting the disclosure of records without the written consent of the individuals is essential unless one of the twelve disclosure exceptions listed in the PPACA applies. There needs to be a thorough look at integrated health care systems and installation of computer networks by health organizations.

It is mandatory on Information Technology (IT) to meet provider demand for more modern and efficient communication technologies, while maintaining patient privacy and complying with security and regulatory requirements,” as concluded by the team of researchers (Ponemon Institute, 2014). Overpoweringly, respondents of the Ponemon Institute study agree that substantial time is wasted and it is now up to hospitals to embrace technology by coming up with appropriate and compliant approaches. Table 2 summarizes the annual productivity and economic impact of inefficiency in communication and collaboration.

Ponemon Institute (2014) study found three areas of opportunity that can be improved with communication and collaboration:

- Patient Admission: Admitting one patient takes about 51 minutes, which an average of 33 minutes (65 percent) is wasted due to inefficient communications. This translates into an annual loss of about \$728,000 per U.S. hospital.
- Emergency Response Coordination: Coordinating an emergency response team takes an average of 93 minutes per patient. Of this time, an average of 40 minutes (43 percent) is wasted due to inefficient communications. This equates to an annual loss of more than \$265,000 per U.S. hospital.
- Patient Transfer: Transferring a patient to another facility or home care/hospice takes about 56 minutes, if all approvals are given in a timely manner, which an average of 35 minutes (63 percent) is wasted due to inefficient communications. The total annual cost of this waste is about \$754,000 per U.S. hospital (p. 2).

FUTURE RESEARCH DIRECTIONS

At the national level, most nations must reconsider their e-health strategies, according to the new

trends and requirements, to adopt the developed standards, and introduce certification procedures for use of all Information Technology and Communication (ITC) applications in health care (Mihalas, 2014). Potential medical applications in public health and in the “ever-lasting health care reform” determined the creation or development of ITC compartments. The ITC elaborates or develops national/regional strategies for implementation of IT in health care/medical activities (Mihalas, 2014). In European countries, the old trend in biomedical/health informatics was to analyze the courses presented to the students for medical students/computer science students or future Health care Informatics Professionals (HIPs) (Mihalas & Lungeanu, 1997). The new trend is numerous European countries introducing doctoral level degrees in medical informatics. This includes a universal approach to medical informatics courses and specialized medical/health informatics schools being at both undergraduate and master levels (Hasman, Mantas, & Zarubina, 2014). Continually, IT applications refer to ‘big data’, which is the enormous amount of data collected that requires applicable infrastructure such as cloud computing, as an impression on countless ITC applications in health care. This includes the national health care plans and strategies (Shimrat, 2009).

During research studies mobile devices were shown to improve communication between doctors and nurses on inpatient wards (Ozdalga, Ozdalga, & Ahuja, 2012). A study by Wallace, Clark, and White (2012) of medical school health care providers and students revealed that over 80 percent of those who responded described using mobile devices to communicate with colleagues about patient care via e-mail, telephone, and text messages. According to Mickan, Tilson, Atherton, et al. (2013), doctors have reported that the use of a mobile device for retrieving information from drug databases led to more efficient decision-making and patient care. They discovered that mobile devices have the ability to increase quality of patient documentation through fewer errors, more

complete records, rapid access to new information, and improved workflow patterns (Mickan, Tilson, Atherton, et al. 2013).

There should be further research on smart devices and their capabilities in communication, assessing, and documenting patient information. It is important to look at the future and the use of medical or health care systems applications becoming more useful in the prevention and management of chronic health conditions, such as diabetes, obesity, and heart diseases. Electronic health applications are electronic tools that utilize information technology to store, manage and share health information (Tang, Ash, Bates, Overhage, & Sands, 2006). One of the most widely known electronic health applications is EHRs, which is an official health record that is digitized for patients to be shared across multiple health care organizations. Mobile device hardware and applications should continue getting better and more user friendly, bringing additional and enhanced benefits to clinical practice (Mickan, Tilson, Atherton, et al. 2013).

CONCLUSION

This chapter investigated the trends in health care information technology and informatics related to patient care. The chapter consisted of the following sections: background; issues controversies, and problems; solutions and recommendation; and future research directions in health care. The term smart devices will be used interchangeably with mobile devices such as smart phones, tablets and iPads; each commonly used by the general public which includes health care providers. Not all health care providers are eager to adopt mobile devices even though they have the potential to increase access to point-of-care tools that has been proven to support better clinical decision-making and improved patient outcomes (Divali, Camosso-Stefinovic, & Baker, 2013).

Information and time management has been the most frequent uses for mobile devices. Popular information management applications, such as Evernote and Notability, allow users to write or dictate notes, record audio, store photographs, and organize material into categories within a searchable electronic database (O'Neill, Holmer, Greenberg, & Meara, 2013). This allows for better documentation of patient records. Research has indicated that mobile devices improve the completeness and accuracy of patient documentation (Payne, Wharrad, & Watts, 2012). Mobile devices were judged higher than documentation using paper records (Mickan, Tilson, Atherton, et al. 2013). Ultimately, their study found a significant increase in the average rate of electronic prescribing, from 52 percent to 64 percent ($P = 0.03$) with the use of mobile devices (Mickan, Tilson, Atherton, et al. 2013).

KEY TERMS AND DEFINITIONS

American Recovery and Reinvestment Act (ARRA): Had three immediate goals: to create new jobs and save existing ones, to spur economic activity and invest in long-term growth and to foster more accountability and transparency in government spending (Blumenthal, 2010).

Clinical Effectiveness: Application of interventions which have been presented to be effective to appropriate patients to improve patients' outcomes and value for the use of resources (National Institutes of Health, Health & Human Services, 2014).

Gross Domestic Product (GDP): Represents the monetary value of all goods and services produced within a nation's geographic borders over a specified period of time.

Health Information for Economic and Clinical Health (HITEACH) Act of 2009: Requires certified Electronic Health Records (EHR's). This requires providers to commit continued use of EHR technology over a period of years. There are no measurable thresholds and programmatic timelines (Joseph, Sow, Furukawa, Posnack, & Chaffee, 2014). However, the certification process for EHR vendors has reduced provider uncertainty

by establishing an unbiased validation service to ensure that certain functionality is available. Providers have to meet certain criteria of “meaningful use”. To an extent that has put the market and not the federal government in determining the vendors that will meet the provider needs with the financial incentives (Joseph, et al., 2014).

Health Insurance Portability and Accountability Act (HIPA): Act created by the U.S Congress in 1996 that amends both the Employee Retirement Income Security Act (ERISA) and the Public Health Service Act (PHSA) in an effort to protect individuals covered by health insurance and to set standards for the storage and privacy of personal medical data.

Patient Protection and Affordable Care Act (PPACA): The health care interrelated portions of the Health Care and Education Reconciliation Act of 2010 and the Student Aid and Fiscal

Responsibility Act were also affirmed into law end to end with the PPACA. These Acts seek to overhaul the current healthcare system. “Obamacare” H.R. 3590, or Affordable Care Act (ACA) for short turned out to be the largest renovation to healthcare reform since Medicare/Medicaid which was signed into law in 1965 (Obamacare Facts, n. d.).

Privacy Act of 1974: This act “protects records that can be retrieved by personal identifiers such as a name, social security number, or other identifying number or symbol” (HHS, n. d.).

System of Records Notices (SORNs): “Required health organizations to create and maintain SORNs. “A system of records consists of any item, collection, or grouping of information about an individual, where those records can be retrieved by the name of the individual or by some other type of identifier unique to the individual” (HHS, n. d.).

User Resistance to Health Information Technology

Madison N. Ngafeeson

Northern Michigan University, USA

INTRODUCTION

The vision to use information technology (IT) in healthcare to improve outcomes has been adopted by many a nation, including, the United States. If effectively implemented and efficiently leveraged, these technologies will greatly lower healthcare costs, improve safety concerns, and elevate the quality of healthcare (Blumenthal & Tavenner, 2010). No doubt, several industrialized nations are making significant investments in healthcare costing a substantial portion of their national gross domestic product (OECD, 2011). Recently, these investments have been in the area of health IT. Socio-economic factors such as aging population, increasing need for better healthcare, and rising health care costs have pressured governments to consider controlling costs while improving care (Romanow, Cho, & Straub, 2012).

Nevertheless, health IT implementation and adoption has met with its fair share of challenges. Reports show that physicians, nurses and other healthcare professionals continue to resist the use of technology within healthcare (Laumer et al., 2016; Dinev et al., 2016; Petrakaki et al., 2016). Researchers have proposed models to explain the *how* and *why* of user resistance to IT, and till date, there still is a lack of an overarching paradigm through which to examine this phenomenon. Hirschheim and Newman (1988) noted that resistance is a complex phenomenon which defies simple explanation and analysis; thereby requiring well-accepted theories or paradigms encompassing the full range of variables associated with an individual user's resistance of IT (Martinko,

Henry & Zmud, 1996). If not for anything else, governments and the healthcare sector need a return on investment on these systems that have been implemented. Understanding and mitigating user resistance is a clear step forward in improving sector-wide adoption.

This paper surveys extant literature on resistance, synthesizes its theories, and provide a paradigmatic lens for leveraging this knowledge in the practice of healthcare IT implementation. It is hoped that this study will not only increase theory-based understanding of the subject, but that it will provide managerial guidance for change managers and project leaders who live the effects of user resistance in practice. The rest of this paper is structured thus: a methodological as well as contextual background of the paper is set forth, the theories of resistance are then synthesized and analyzed, and the implications of the study are discussed.

BACKGROUND

In order to delimit the scope of this research, to synthesize and to analyze extant literature, we use Cooper's (1988) taxonomy of literature reviews. This model (Cooper, 1988) proposes a taxonomy of reviews based on six categories, namely: the focus, goal, perspective, coverage, organization, and audience of the literature. Given the objective of this study, the literature was reviewed with varying emphases based on Cooper's taxonomy. To achieve this, the review focused on different theories and models of resistance, and highlight the unique perspectives that these theories offer about

the phenomenon. First, we discuss a contextual background in the United States healthcare reform that has triggered nation-wide organizational change leading to resistance.

The Meaningful Use Reform and Change

On July 13, 2010, the United States administration rolled out a five-year transition plan for the U.S. healthcare industry to move from paper health records system to electronic health records. Over a ten-year period, the U.S. government plans to invest about \$70 billion to help the healthcare sector in this transition process (DHHS Press Release, 2010). This governmental mandate has been named, the Meaningful Use policy. It is arguably the greatest organizational change trigger in the U.S. healthcare system to date. Summarily, this reform program set the standards for health IT definitions, guidelines, and implementation.

The introduction of HIT into the healthcare industry has been associated with distinctive changes. Lorenzi et al. (2000) describes possible changes that typify healthcare organizational change namely:

- Operational changes. These affect the way the ongoing operations of the business are carried out, such as the automation of a particular area.
- Strategic changes. These occur in the strategic business direction, e.g., moving from an inpatient to outpatient focus.
- Cultural changes. These affect the basic organizational philosophies by which the business is conducted, e.g. implementing continuous quality improvement system in a clinical environment.
- Political changes. These involve staffing that occur primarily for political reasons of various types, e.g. those that occur at top patronage job levels in government agencies.

THEORIES AND CONCEPTUALIZATIONS OF RESISTANCE TO IT IN RESEARCH

H

User resistance to information technology is defined as a user's insistence to not use new IT. It is seen as a user's attempt to minimize his or her outputs while attempting to maximize and increase others' inputs (Joshi, 1991). This resistance, according to Markus, (1983) may range from subtler manifestations of resistance as passivity, misuse, low levels of use, and lack of use to harmful use (Marakas and Hornik, 1996; Martinko et al., 1996; Selander and Henfridsson, 2012). Marakas and Hornik (1996) discuss a form of resistance in which behaviors take "the form of overt cooperation and acceptance of the proposed system combined with covert resistance and likely sabotage of the implementation effort" (p. 208). Lapointe and Rivard (2005), on the other hand, mention the more overt side of resistance with scenarios where users "delivered an ultimatum, demanding that the system be withdrawn" (p. 477). In this study, resistance refers to covert or overt behaviors that oppose change towards the use of- or avoidance of an information system manifested as reactance, distrust, scrutiny or inertia (Ngafeeson, 2013).

The Interaction Theory

Markus's (1983) pioneering research in user resistance to information systems (IS) is arguably the departure point for most IS resistance research. Her seminal work basically responded to the question as to *why* people resist IS. Three types of theories are proposed: first, people are said to resist technology because of internal factors inherent in those who resist or their organizations. Second, resistance stems from external factors emerging from the introduced system. Lastly, resistance may also stem from the interaction of both internal and external factors. Markus termed the latter, the "interaction theory." While the theory of the interaction between the subject

of resistance and the object of resistance was not entirely new, Markus's work discusses this theory within an IT context.

Arguing from a group level and organizational level perspective, Markus (1983) demonstrates the importance of the interaction theory in understanding user resistance to information technology. Markus established a model which showed the interplay of power within the organization following the implementation of a new system. According to Markus, the interaction of an individual's characteristics with the specific system design features and the organizational context will determine user resistance. Markus then describes and evaluates these sets theories based on the underlying assumptions and tests them with data from a case study. Results showed that the interaction theory was a superior theory for explaining resistance for implementers than just from the technology or from the individual/organizational perspective.

Markus contends that the interaction theory is important in analyzing, diagnosing and finding solutions to organizational resistance to change introduced by information technology. This conceptualization, however, is limited in two significant ways: it views resistance from purely a political sense, and is likely to be more applicable for systems that are implemented across departments (Joshi, 1991).

The Equity Implementation Model (EIM)

Another significant theoretical model, the equity implementation model (EIM), was posited by Joshi (1991). Derived from the equity theory, the EIM attempted to explain resistance to change from a fairness perspective. The EIM proposes that individuals attempt to evaluate most changes. The changes considered as favorable are generally welcomed, while those considered as unfavorable are likely to be resisted. In a similar way, the equity theory suggests that in an exchange relationship, individuals are constantly concerned about inputs, outputs and fairness of the given exchange.

Hence, individuals are continuously comparing themselves with referent others and peers to assess if net gains are same. When these persons, therefore, experience a net loss in equity, the equity theory suggests that the people are likely to become distressed. This distress caused by inequity then leads the concerned individual to resist the change by lowering his or her inputs while trying to minimize the outputs of others. Building on the equity theory, Joshi (1991) proposed a three-level analysis of equity namely: a comparison of self with self, a comparison of self with employer, and a comparison of self with co-workers. According to the EIM, users will resist use, if inequity was perceived at any of these three levels, following the introduction of a new system.

In summary, EIM postulates that people analyze equity at three major levels, namely: at *self*, *organizational*, and *peer* levels. At level one (*self*) equity evaluation, individuals compare their inputs with outputs and calculate their net gains. If the new system brings with it net gains in equity such as less tension and better working conditions, the individual is more likely to embrace the change. On the contrary, if the system brings the individual a net loss in equity such as loss of seniority or increased workload, then the individual is likely to oppose change. At the second level of equity (*organizational*) evaluation, an individual compares equity net gains, in much the same way as at the first level: only this time, the individual compares their personal net gains to that of the organization. If the net gains are positive, change is welcome; but if the individual perceives that the organization's net gains are more than theirs, resistance is likely to result. A third level of analysis (*peer* level) is also proposed in which an individual compares their net gains with those of their peers and referent others after the introduction of the new system. Here, the user asks questions like: "Does the new system treat each user equitably? Or, does it increase others' equity while lowering those of others?" If the assessment is that personal equity is increased, change is received; otherwise, it is resisted.

A possible critique for using the EIM as a stand-alone model for explaining resistance is that inputs and outputs are difficult to name and measure. This is especially so because these inputs and outputs could be tangible as well as intangible—the measure of which might be as challenging as impossible. As Joshi (1991), himself, states: “the nature of changes may also make it difficult for users to make objective assessment.” This suggests that, a need for a model that would be sensitive to other types of changes is a welcome necessity.

The Attributional Model of Reactions to IT (AMRIT)

Martinko, Henry and Zmud (1996) begin their theory-building process on the premise that, hitherto, there had not been any “well accepted theory or paradigm encompassing the full range of variables associated with an individual user’s resistance of IT” (p. 313). Drawing from extant research in social psychology and organizational behavior, Martinko et al. (1996) proposed an attributional model to explain IT resistance (AMRIT). Based on previous literature that utilized the attribution theory and learned helplessness, Martinko and associates develop a model that they suggest could serve as a “basis for a more comprehensive theory” of worker resistance to the introduction of new technology in the workplace. According to the attribution theory, an individual’s behaviors are a function of his or her beliefs about the possible outcomes. More specifically, it looks at the perceptions of what causes these outcomes. The AMRIT posits that individuals’ attributions are informed by their experience with successes and failures. It suggests that individuals interpret their behaviors in terms of the causes. Consequently, their behaviors in the future are constructed from the expectancy that comes from these attributions. In other words, success or failure with prior implementation of a technology may cause implementers to develop

certain attributions to why this happened. These attributions then create certain expectations with regard to the technology’s efficacy, leading to behaviors or feelings about the system that can be either negative or positive. Like many of the other models before this one, the Martinko et al.’s (1996) model shed more light on the nature of IS user resistance; however, this conceptualization ended at a purely conceptual level.

The Lapointe and Rivard (2005) Model (L-R)

Lapointe and Rivard (2005) examined group resistance dynamics at three levels namely: pre-implementation, during implementation, and post-implementation of an IS. The L-R model was developed to explain a multilevel dimension of resistance to IT implementation; arguing from the perspective that previous models had only looked at resistance at one level of the organization instead of examining different levels of the organization. Building on existing research, the L-R model, has proven to be an important model for a closer examination and extension. In summary, the L-R framework posited that resistance to an information system results from perceived threats which in turn evolve from a complex interplay of political and interpersonal/group factors resulting from people’s interaction with an IS. Lapointe and Rivard (2005) termed these “interaction effects”, initial conditions. Simply put, when an individual or an organization interact with a newly installed technology in the workplace, resistance targeting either the technology itself, the advocates of the technology or the significance of the technology may result. The L-R model also posited that resistance to information technology is mediated through *perceived threats*. The L-R model serves as a generic process model that provides a good departure point for more empirical investigation. For one thing, the L-R model incorporates previous frameworks and deals with user resistance from a multilevel and process perspective.

The Status Quo Bias Theory

The status quo bias perspective was proposed by Kim and Kankanhalli (2009). It is one of the few theoretical models of resistance to information technology that has been proposed and empirically tested. Kim and Kankanhalli (2009) contended that people resist an information system due to their desire to stay in their current state or *status quo*. In other words, people exhibit a bias towards maintaining their “old habits” when confronted with the choice of change (see Hsieh, 2015).

In the context of technology-enabled change, therefore, the *status quo* bias perspective holds that people may resist the implementation of new technology, for the sole purpose that they are comfortable with the current state. Because of this desire to maintain the *status quo*, they judge the decision to change as a cost associated with this change, rather than the benefits thereof. By testing their model within the context of a new enterprise system, Kim and Kankanhalli (2009), found that the cost of switching to a new system from an old one caused user resistance. The attempt to empirically test user resistance of IS was probably the hallmark of Kim and Kankanhalli’s (2009) work.

IT Conflict-Resistance Theory (IT-CRT)

Situating their research within a pre-implementation context, Meissonier and Houzé (2010) propose the IT conflict-resistance theory and use the framework as a basis for a two-year action research project. The research suggests that pre-implementation resistance to IT could be used as a gauge to assess possible post-implementation concerns. Resistance in this sense, therefore, is seen as positive tool for technology acceptance in the post-implementation phase.

Like previous works, Meissonier and Houzé (2010) highlighted socio-political factors as well as task-oriented factors as salient determinants of conflict and resistance. However, being an action

research in itself, the conceptual model proposed, suggests a more heuristic and practical approach to the topic than a testable concept.

Cynicism Theory

Selander and Henfridsson (2012) conceptualized *cynicism* as resistance. Building on the Lapointe and Rivard (2005) process framework, Selander and Henfridsson (2012) propose three dimensions of user cynicism as the precursors of resistance. They argue that cynicism is a remote form of resistance that is not mediated through *perceived threats*, but is rather manifested as a form of *passive resistance*. They also suggest that cynicism, being a passive resistance in itself, could escalate to other forms of resistance. The three dimensions of cynicism conceptualized were *cognitive distance*, *negative affect*, and *seeing through espoused claims*. *Cognitive distancing* here refers to the way employees of an organization alienate themselves from the management’s policies and stance. *Negative affect* on the other hand is defined to involve negative emotions towards managerial behavior including defeatism, betrayal, and disillusionment. *Seeing through espoused claims* supposes that the employee possesses knowledge of how things could better be done and is aware of managerial inconsistencies and repudiates these assertions.

In sum, Selander and Henfridsson (2012) contend that these three dimensions of user cynicism constitute a form of *passive resistance*. Using this framework, they built upon the Lapointe and Rivard (2005) framework. Their work however deferred from the Lapointe and Rivard model in that it completely ignored *perceived threats* as mediator between *initial conditions* and *resistance*. Like other models before it, it remained at a purely conceptual level: suggesting three antecedents of user resistance, but going no further.

Alternative Theories of Resistance

The following section discusses theories that either have been used to explain user resistance,

but have not been leveraged in IS literature, or theories that inform our knowledge of user resistance, albeit not fully. Some of these theories include: the technology acceptance model, the psychological reactance theory, and the cognitive dissonance theory.

The Technology Acceptance Model (TAM)

TAM has been used to predict user acceptance of technology in different IS studies (Venkatesh & Davis, 2000; Mathieson, 1991). TAM is based in the *theory of reasoned action* (Fishbein & Ajzen, 1975) and is now widely regarded as the standard model for examining *technology acceptance*. Because of the failure by employees to accept and use technology, organizations as well as technology vendors see *user acceptance* of technology as crucial to organizational survival. The TAM in its simplest form suggested that *perceived usefulness* and *perceived ease of use* would predict *user acceptance* of an information technology. In other words, Davis (1989) posited that the acceptance or rejection of a technology is a function of how individuals perceived that the technology would be either useful or how easy it could be to use the given technology.

The Psychological Reactance Theory (PRT)

Another alternative explanation of resistance is the PRT. Brehm's PRT is one of the most widely accepted resistance theories in social psychology. It has also been widely used to explain resistance and persuasion—its antithesis. PRT is built around the notion of “free behaviors” and “freedoms” It assumes a “conservative stance on people's desire for change” (Brehm & Brehm, 1981, p. 25). The PRT is based on the assumption that individuals generally believe that they have specific *behavioral freedoms*. When these freedoms are threatened,

individuals are aroused by the motivation to reassert their freedoms. The *psychological reactance theory* assumes that people's behaviors are motivated by the desire to protect their “freedom” to carry out a particular behavior in a particular context. This “protection” of freedoms is then manifested as resistant behaviors.

The Cognitive Dissonance Theory (CDT)

This theory holds that, “when an individual holds two or more elements of knowledge that are relevant to each other but inconsistent with one another, a state of discomfort is created” (Harmon-Jones et al., 2010). The resulting discomforting state is called *dissonance*. Because dissonance originates from the conflicting views or beliefs about one's self, the term *cognitive dissonance* is used to collectively describe the concept (Festinger, 1957; p. 9). According to the dissonance theory, this inconsistency or “lack-of-fit” of cognitions motivates the individual to be involved in a psychological effort to reduce the inconsistency between the cognitions. It is this effort to reduce inconsistency that leads to *resistance*.

According to the *cognitive dissonance theory*, user resistance can be conceptualized as follows. When an individual's intention or action to reduce inconsistency is to rationalize or support his present state of cognition: such that “new knowledge” is considered as dissonant with the individual's present cognition, the consequent behavior can be described as resistance. Simply put, resistance is an implicit or explicit intension that results to a behavior that opposes change towards a particular “new” attitude or behavior. Notwithstanding, the CDT has shortcomings. Harmon-Jones and Harmon-Jones (2002) argued that Festinger's (1957) theory stopped short of explaining *why* individuals do not like to be in a state of cognitive inconsistency.

IMPLICATIONS AND FUTURE RESEARCH

This study examined user resistance to information systems from several theoretical angles within the wider context organizational change. The claims and assumptions of relevant extant theories and models were specifically discussed. The results of the synthesis of resistance to information technology literature can be summarized as follows:

- Resistance is a complex phenomenon: requiring different theorizations for a more comprehensive understanding.
- Resistance attitudes should be studied from an unbiased perspective: that is, not regarding resistance as either positive or negative; rather, letting the context define its nature.
- Resistance attitudes may last through pre-implementation, implementation, and post-implementation phases of an information system.
- Resistance behaviors could originate from a single individual as well as groups of individuals.
- Resistance is a result of the dynamic interaction between people, technology and the processes and procedures within an organizational environment.

In general, this research showed that there is a lack of an overarching paradigm of user resistance to information systems in spite of the burgeoning alternative theoretical explanations of user resistance to IT that have been proposed. Second, there is a noticeable lack of empirical investigations. Most of the research so far has been dominated by case studies, action research and other qualitative methodologies. Consequently, many of the proposed models are yet to be validated. Third, not many studies have specifically looked into user resistance in the context of health information technology. Lastly, with the several theories

and perspectives already proposed, there still is a lack of a comprehensive theoretical framework that can be tested.

Theoretical and Practical Implications of Research

This work offers implications and contributions to theory. First, the study extends the body of literature by combining social psychological theories, information systems theories and a policy framework to explain the concept of resistance. It broadens our understanding about user resistance by introducing social psychological theories that are often not leveraged in information systems to explain resistance. As has been argued by other researchers before, resistance needs to be addressed from a more comprehensive theoretical standpoint. Future research can incorporate these theoretical perspectives to better understand resistance to IT.

The study also has implications for practice. In a healthcare environment fraught with technology-induced organizational change, change managers' understanding of the importance of resistance is critical. Knowles and Linn (2004, p. 9) have suggested that understanding resistance, would shed light about the role of persuasion—its antithesis. Persuasion is seen as a very important antidote to resistance. Persuasion skills are expected, if not required of change managers' portfolio of abilities. This study provides change managers with empirically tested knowledge for decision-making.

Overall, this study points to the critical role of organizational support in the change management process. Management would need to provide sensitization, guidance, training and opportunity for employee feedback before, during and after the implementation of a new system. Just as some researchers have recommended, top management support in organization-wide implementation is critical (DeLone, 1988). Reducing threats and mitigating resistance will clearly require the need for management support.

Suggestions for Future Research

Future research could use this study as an important departure point to answer some important questions: (1.) Do specific *threats* lead to specific dimensions of user resistance? (2.) Are there more types of perceived threats that are salient to IT user resistance? (3.) Are there any other theories that can inform our knowledge on possible *initial conditions* yet to be uncovered? These are some areas in which future research could take. Additionally, finding which type of *threats* and *initial conditions* contribute to resistance during the different stages of implementation could be particularly insightful. For example, if individual factors were found to be particularly associated with user resistance during the pre-implementation phase, then, change management programs could be designed to target causative initial conditions.

CONCLUSION

The introduction of electronic health records into the United States healthcare system is expected to increase legibility, reduce medical errors, shrink costs and boost the overall quality of healthcare. Early field reports about this transition reveal that healthcare professionals including physicians and nurses are resisting the full use of these systems. This study proposed key theories from social psychology, and information systems to provide a multi-perspective look at the concept of resistance to information technology. These theories, together, explain and expound on resistance in a way that can increase our understanding. The application of these findings has the potential to improve the chances of successful IT implementation within the healthcare industry in particular.

KEY TERMS AND DEFINITIONS

Cognitive Dissonance Theory: The theory suggests that when there exists a “lack of fit” of cognitions, a state of discomfort called *dissonance* is aroused, triggering a reaction to reduce it.

Cynicism Theory: Proposes a passive form of resistance that is not manifested through perceived threats.

Interaction Theory: Proposed by Markus (1983), it proposes that IT resistance stems from the interaction between people, the technology in question, and the environment surrounding the technology.

IT User Resistance: The overt or covert attitude or behavior towards an IT system resulting in avoidance, underuse or outright nonuse of an IT system.

Meaningful Use: The U.S. government mandate of 2010 requiring an eligible provider to use certified technology to meet specified government benchmark outcomes.

Psychological Reactance Theory: This theory posits that when individual freedoms are threatened, and uncomfortable emotional state is created that necessitates a return to “normal”, which may manifest as resistance.

Status Quo Bias Theory: Posits that, people, who are comfortable with the current state of affairs, may resist the change that will ensue following the implementation of a new system.

Androniki Kavoura
Technological Educational Institute of Athens, Greece

INTRODUCTION

The aim of this chapter is to: (1) present a review of some innovative communication technologies in higher education and how these are implemented for organizational, marketing and learning processes, (2) illustrate how Information and Communication Technologies (ICTs) may drive the introduction and use of plethora of inventive activities in education.

Current trends in higher education institutions (HEIs) are associated with supplying the student with those learning methods that can lead to skills and contribute to his/her creative and individual thought (Cuenca et al., 2015). At the same time, teaching instructors need to be aware of the know-how in the communication and information technology sectors that can be further employed in different fields of research. In parallel the use of new technologies in the delivery of courses offers HEIs competitive differential advantages.

Financial cutbacks and limited government support for institutions of higher education, led to: (a) either a withering effect for them that shrink or merge in order to survive or (b) find innovative ways to survive and attract new students and audiences as potential users while making con-

nections with the community and firms (Bowen, 2013). The implementation of innovative communication technologies with the use of ICTs via computers, mobile phones, telephone lines to access and manage electronic data on the web allows users to actively participate in the learning process, provides lifelong learning opportunities and offers a competitive advantage to HEIs that have not fully implemented the possibilities on offer. HEIs may further adopt ICTs to communicate and promote their services on offer to attract existing and potential audiences but also to initiate technologies in order to provide the most updated tools for their learning process. Virtual and online learning processes cannot substitute for the physical experience, nonetheless, they may contribute to its enhancement.

For innovation to take place in higher education, the organizational culture of institutions of higher education and leadership should support such initiatives (Zhu, 2015).

This chapter presents an overview of the technological advances that enhance communication and strengthen innovation in higher education. A review of literature along with the use of popular business sources provides an as-is on the topic.

BACKGROUND-THE USE OF NEW TECHNOLOGIES AS A MARKETING TOOL IN HIGHER EDUCATION

The Organizational Perspective

The flexibility in using new technologies in HEIs is reflecting the socio-economic changes affecting the needs of the student population across the world (Narduzzi & Campbell, 2015). The characteristics of students are continuously evolving reflecting expectations for increased mobility, distant-learning, internationalization of the curricula and the introduction of new disciplines of study. New technologies such as learning management systems (LMSs) and web-based learning programs (BlackBoard Learn, Moodle, Brightspace by Desire2Learn(D2L), etc.) that extend to applications available on handheld devices such as BlackBoard Learn-Mobile Learn, Collaborate, Podcasts and iTunes U, or user-generated content (Wikipedia, Youtube, etc.) address some of the needs of learners. These applications offer some access to the functions available in the full-version web-based platforms. The mobile applications serve as enhancers rather than a mobile equivalent to the LMSs platforms.

The LMSs provide institutions with the advantage of offering credit-bearing instruction online. Access to these is course-specific and requires the use of a username and password available through an academic course provider. Using LMSs, schools enhance existing courses, offer hybrid options and/or introduce entirely online classes and programs of study.

Blackboard Learn in particular is a learning management system that offers both the capability of offering educational courses online and managing a learner's account through the same platform. It becomes a useful tool for online learners or students' on the go. Blackboard is a paid service.

Moodle is an unrestricted and open-source software that was introduced as a means to enhance courses or used a tool for hybrid courses taught partially in a classroom setting and partially on-

line. This is now the world's second most popular learning management system after Blackboard.

Brightspace by D2L, is another popular learning management system, providing an alternative to Blackboard and Moodle.

A number of free non-credit-bearing applications are used to enhance and compliment courses. iTunes U is such an application available on apple's iTunes store. Universities and schools across the world are able to create school-specific applications and content available to a worldwide audience.

Wikipedia and YouTube are both free worldwide user-generated platforms. Wikipedia is one of the world's largest user-generated content platforms referred to as an encyclopaedia. This cannot be considered as a scholarly source of reference due to its content-generation principle.

YouTube is a video-sharing platform that allows individuals and organizations to upload and share video clips, music clips, etc. Often academic establishments use YouTube to share lectures, seminars, product demonstrations or training videos.

Marketing and public relations departments of HEIs in charge of promoting and communicating to the public the institutions and services available are implementing new technologies and the use of internet in order to cater for existing and potential students' needs who are adept in internet applications (Siamagka & Christodoulides, 2016). In that way, people become aware of the methods and techniques on offer by HEIs and this may attract more potential students in the institutions that provide and promote innovative services and methods related to higher education. The tools could be implemented to promote the educational institutions and their activities. Both national and international students can be attracted while online learning can enhance collaborations between institutions.

In parallel, new technologies allow HEIs to cater for:

1. Accreditation needs (State, country, or by independent agencies – AACSB for Business schools, etc.).
2. Marketing and promotional activities (internally to current students, externally - alumni, prospective students, etc.). This strengthens the institutional brand and provides tangible advantages (Khanna, Jacob, & Yadav, 2014).
3. Promoting and enhancing healthy competition among institutions.
4. Societal changes and new trends by presenting an image of care to the student population.

The use of new technologies by HEIs gives education establishments a differential advantage (see Table 1). It also creates open, mobile, flexible and accessible educational experiences that cater to the needs of the learner on-the-go. In particular, new technologies are used as an enhancement or extension of courses that target a wider audience of learners. In addition, they provide a virtual learning environment and help with the enhancement of courses and training with digital media and make it easier to provide learner feedback regarding tracking, reporting and managing a learner's account.

The User's Perspective

Higher education aims to provide competencies to students associated with their ability to communicate and handle different scenarios throughout their lives by using creative tools while working as part of a group (Cuenca et al., 2015).

HEIs must continue to experiment and share best practices in providing students with high quality learning experiences that are globally engaging, intellectually rigorous, and personally rewarding. This is part of a growing global trend that recognizes new technologies in their enhancing knowledge availability and retention (Bulfin, Pangrazio, & Selwyn, 2014) (see Table 2).

Innovation competency is associated with the ability of students to make self assessments via learning methods acquired that will help them to

Table 1. Advantages and disadvantages of the use of innovative technologies in HEIs from an organizational perspective

Advantages	Disadvantages
Marketable advantages (Competitive advantage in competition)	Variability and complexity of technological advances
Flexibility & accessible education on-the-go	Time invested to learn and use
Enhancement or introduction of new courses	Compatibility with other forms of technology and existing infrastructure
Administrative ease (managing a learner's profile)	Applicability and sustainability issues

Table 2. Learning advantages and disadvantages of new technologies from a user's perspective

Advantages	Disadvantages
Enhancement of creativity and innovation for the user	Increased workload
Flexibility when and how to participate in the educational programs	Social and communication skills may become less cultivated. The dynamic result of teamwork may be significantly reduced
Encouragement of knowledge retention (Enthusiasm)	The individual needs to be adept with innovative tools in order to employ them
Ease of self-assessment and monitoring of progress	The personal contact and interaction is missing
Development of personal and professional skills (Confidence)	The individual becomes socially isolated

communicate and interact in multicultural and multidisciplinary environments (Cuenca et al., 2015).

Researchers have highlighted the need of equipping students with the skills to be employable. These may include adapting academic curricula to emphasize skills, introduce and new instructional methods, use information technology, service learning, career planning, students' logbooks, extra-curricular activities, work-based education and other (Asonitou, 2015; Blackwell et al., 2001).

United States of America (USA) students are part time or even full time while raising children

and attending classes and thus, educational programs need to take into account their audiences' needs (Knowles, Holton III, & Swanson, 2014). In addition, there is pressure for embracing further minorities (López, 2015), different races (Hiraldo, 2015) and sustainable academic program development (Adomßent et. al, 2014; Godemann, Bebbington, Herzig, & Moon, 2014).

When educators use new technologies such as handheld computing devices (tablets) as a method of instruction, they create a notion of enthusiasm and hype in class (Nguyen, Barton, & Nguyen, 2015). This boosts student confidence and strengthens their willingness to embrace new learning technologies. The adoption of new technologies in HEIs is also faced with some skepticism by some (Muller, 2014), as there are fears that it may interfere with the student workload (Gregory & Lodge, 2015) (see Table 2).

Based on the fact that academic programs are not geographically defined anymore, initiatives have developed so that both teaching staff and students can benefit. In Australia for example, emphasis has been put on teaching staff's professional development where through open line courses, professors share knowledge with another all over the world in regard to educational design (Mirriahi et al., 2015). Staff interacts, improves digital literacy and shares knowledge.

The tools presented in the next sections may be to value for both students and teaching staff but also to the society and community where universities are located based on the innovation that is transmitted there. Academics may implement social media to approach students. This has taken place in many cases with a successful engagement between student staff communication of ideas (Sessa, 2014).

Technology Transfer

Cooperation between universities and/or firms is often associated with patenting and licensing of academic inventions and their connection to

industrial innovation; this brings forth the technology transfer element (Mowery, Ielson, Sampat, & Ziedonis, 2004). Among the technology transfer mechanisms patents, copyrights, trademarks, licensing agreements between the university and private firms, university-based start-ups but also technology parks are incorporated (Link, Siegel, & Wright, 2015). In regard to US Universities, the Bayh-Dole Act allowed the use of University laboratories to implement technological advancements that can be further useful to communities and firms (Link et al., 2015; Mowery et al., 2004). Since there are financial cutbacks, universities have an alternative way to find sources through research and technology (Siegel & Wright, 2015). There is room for further growth regarding technology transfer in HEIs pertaining entrepreneurship opportunities (Lackéus & Middleton, 2015). The necessity for technology transfer could bring together academic expertise and streamline this with industry needs (Wright, 2014).

Medical research centers of Universities are known to excel at technology transfer among past and current trainees and scientists. As an example, Emory University in Atlanta, USA has developed tools and invested in infrastructure that enables technology transfer. The development of the Emory Cardiac Toolbox software is an example of this approach.

Innovation is created within the technological parks of the Universities. It is typical to note that this is usually the result of teamwork that can be developed as part of the generic competencies of those involved.

The teamwork that is created within the technological parks of the Universities is a miniature of the real world. These students will work in the market, in companies and they need to handle skills and competencies that have learnt while participating in higher education's environment. That is why, project team work may result in technological innovation and participants in technology transfer, need to find ways and skills to cooperate with each other as a significant at-

tribute of their behavior that leads them to work for technological innovation (Vick, Nagano, Author Vitae, & Popadiuk, Author Vitae 2015).

It has been found that the workforce that is consisted of similar high educational background, illustrates a positive innovation performance (Subramanian, Choi, Lee, & Hang, 2015). We should also take into consideration that when many people work in a project or in an office as those specially designed for technology transfer, conflicts may arise. Teamwork and sharing of responsibilities may prove to be of help for this sector of research.

Win-win solutions from business communication and social psychology theories where all the participating parts in the technology transfer, both the higher education institution and the management of the business that are involved in the technology transfer (O'Kane, Mangematin, Geoghegan, & Fitzgerald, 2015).

Libraries can also be a valuable partner in universities for implementing innovation and transfer knowledge. Hoppenfeld and Malafi (2015) argue that there is an initiation of cooperation with centers of entrepreneurship and two public and academic libraries in Texas; they promote their resources and databases for this reason to the public but also to students interested in engaging with entrepreneurial activity.

Experiential Learning and ICTs

Experiential learning is associated with the uncover of subjective experiences at a setting where the learner has direct contact with the phenomenon under examination; thus, learners bring into perspective the content of what is presented in the curriculum via the courses and they do not have to create ideas from scratch (Bublitz & Philipich, 2015).

Other areas that can initiate and employ knowledge transfer exist within HEIs that include experience-based education, internships and cooperative learning experiences. In these cases, students benefit from working with an outside

organization, applying theory and processes learned as well as acquiring business skills in practice. Some HEIs require student to complete such a program during their third year of undergraduate studies. This enables students to bring back to class professional skills and excel at the remaining duration of their studies.

Mobile and technology-based learning, digital game-based-learning, innovative e-learning strategies or tools in web information, the use of tablet PCs (TPCs) in classroom instruction can contribute significantly so that technology is employed for the student's active participation in learning activities (Hung et al., 2015)

Internship programs or work-placements have been recognized as one of the most efficient methods to bridge the gap between education and employment requirements (Asonitou, 2015).

The knowledge acquired while in university based on the theory gained from the study program, can be combined with practice through projects associated with a working environment. This enables students to get used to teamwork and to develop skills that are necessary in order to be competitive in the market (Sulas & Baynar, 2015).

In order for surgical educators to be able to communicate and exchange ideas between peers WIGGIO is an online networking and collaboration tool that brings people with similar professional and scientific interests together and had been implemented at the Montreal General Hospital Canada. Petrucci et al. (2015) found that in fundamental laparoscopic surgery, WIGGIO in fact, improves manual skills based on simulator experience and training but also with the use of video since members of the groups interact with each other and exchange ideas about scientific papers that they could read while post online important events on the online calendar so that all members can be informed about them.

Another experiential learning example takes place in the Georgia Institute of Technology that organizes the Georgia Tech (GT) Convergence Innovation Competition (Georgia Tech, 2015). The Georgia Institute of Technology initiates the GT

journey that calls participants to develop mobile, web and desktop applications with the contribution of resources of the camp and community, industry and academic support. All these support student innovation as a living lab (Sanders et al., 2015). The Convergence Innovation Competition (CIC) is a semester long event that motivates students to use laboratories, professors; guidance, industry's guidance and campus resources in a lab space in order to create innovative products and experiences. This form of a living lab can be associated with experiential learning and at the same time, allows for technology transfer.

Among the best practices presented in experiential learning, is the application of theory to practice via for example, the student hands on experience with the run free clinic that was created in association with the University of Michigan in Flint while direct effects to the community emerge (Kruger, Kruger, & Suzuki, 2015).

Learning experiences are congruent with learning styles that in turn influence learning styles while depending on whether the theory base plays a significant and important role, the development of useful devices and processes are implemented or not (Kolb, 2014).

The use of innovative tools can be further used to teach students in higher education how create competitive electronic portfolios with the use of infographics and multimedia tools that can employ sight and sound and create stories for the owners (Haverkamp & Vogt, 2015).

Distance Learning Education and ICTs

Distance education has employed classes in virtual world learning that offers participants learning and emotional experiences and skills (Reinsmith-Jones, Kibbe, Crayton, & Campbell, 2015).

The use of digital mobile devices as a technique of ICT innovation found that when employed in Spanish universities, improved the way of teaching in distance learning but also contributed to generic competencies (Sevillano-García & Vázquez-Cano,

2015). The use of tablets and smartphones in higher education contributes to the development of oral and writing skills that allow people to effectively communicate with each other, the development of teamwork where team responsibilities are allocated with teammates, to develop interpersonal effectiveness where people mingle with different people (Hogg & Vaughan, 2008). Mobile devices are thus, used not for learning reasons but to be able to connect online and be able to collaborate with other people.

Lifelong and Continuing Education and ICTs

The meaning of lifelong learning (Falk, 2014) is continuously evolving considering the accessibility, availability to all and depth of knowledge today's learners have (Head, Van Hoeck, & Garson, 2015). Lifelong learning also accounts for community wellbeing among adult learners (Merriam & Kee, 2014). Current trends suggest that lifelong learning:

(a) helps learners achieve the most up-to-date education, (b) is cost effective, (c) is inclusive and eliminates elimination of learners, (d) supports the creation of a sustainable support system, for learners, (e) can be self-drive and assessed, (f) can accommodate life-work balance (Hanemann, 2015; Neimeyer & Taylor, 2014). The creation of teamwork projects allows individuals to communicate within the work they participate, having the maturity and responsibility to act responsibly.

People can be trained and learn throughout their lives at the right and convenient time and place for them, are motivated to continue to gain knowledge at their own pace, and thus, are able to reach their goals in the community or business environments (Martin & Pear, 2015). Since school in the traditional sense of participating in class for some years when one is a student at a younger age cannot equip learners with all the skills they require throughout their lifetimes, lifelong learning and the implementation of new technologies are adaptable to be convenient for learners, are

personalized and unobtrusive (Zolinas, 2015). Lifelong learning may contribute to smooth group behavior and decision making since the individual will acquire continuous knowledge, resources and skills that may contribute to self-fulfilment and better evaluation of the social world and interpersonal relations (Franzoi, 2012).

Open access courses take place at the higher institution on broader topics and these can be attended by the community that may be interested and benefit from such lectures and open discussions. New technologies allow for such process to take place via web based technologies.

Coursera, a formerly non-credit bearing for-profit massive open online courses (MOOCs) provider has been gradually offering courses for academic credit. It will be interesting to see how this learning platform provider will shape online and distant education in the years to come in comparison to BlackBoard, Moodle and Brightspace by D2L.

Executive Education in HEIs and Innovation with ICTs

Corporate-level learning, often promoted as corporate university, provides personalized reliable education for the benefit of employees and the company (Stephens & Margey, 2015).

A special focus on executive education programs has been given on public administration programs in Egypt (Wafa, 2015).

The working knowledge can be combined with academic knowledge where executive learners aim to understand their workplace as this was the case of executive education in Ireland. Waller and Fawcett (2015) argued for the executive education as an integrator among the whole university.

Combining high quality research from universities and practice consists of a challenge for universities that aim to promote entrepreneurial education that is incorporated in their curricula either within other program or as a distinct program (Vanevenhoven & Drago, 2015).

A custom executive education program charter can be posed as a key task to complete at the outset of a new custom executive education provider/client relationship (Haskins & Clawson, 2015).

Executive education can be either credit bearing or non-credit bearing. This means that learners may seek credit or non-credit as part of a degree or certification program. By attending courses at their own pace and choice that may contribute to their career or personal advancement, individuals get accustomed to teamwork and cultivate their communication skills more since they return more mature to attend classes within higher education. This is how social psychology's courses could approach the graduate mature student in combination with innovative communication technologies.

International Cooperations and Web-Based Technologies in HEIs

Another innovative approach in higher education is the international branch campuses (IBC) that is an organizational model for higher education where borrowing and importing of practices from the cooperating institutions is the norm, creating a cluster model. IBC represents international collaboration and is associated with an institution that is located in another country from the one that initiated IBC and awards degrees in the host country through some physical presence there (Crist, 2015). New technologies substitute for and cover the physical absence by means of communication, gathering and transferring information, attending programs.

Around the Persian Gulf, United Arab Emirates have introduced the first IBC and supports the largest of them by far anywhere in the world based on official reports and studies presented by Crist (2015).

Individuals may cooperate with higher levels in the pyramid such as nations, firms, teams in order to be able to bring innovation and knowledge for the benefit of all (Andersson, Dasi, Mudambi, & Pedersen, 2015).

RECOMMENDATIONS FOR FURTHER RESEARCH

Flexibility is the key term that should be adopted and further searched in regard to higher education that cares for its people and the communities within which it operates, thus, creating a brand.

As HEIs embrace an increasing number of new technologies we will continue to witness change in terms of delivery, access and variety of knowledge.

In addition, the closer interaction of HEIs with industry provides an opportunity for practical applications and executive education.

The axes in higher education in regard to innovation should be threefold, students, teaching staff, implementation of inspiring policies. It is clear that the student community, educators and administrators need to embrace further the technological opportunities available. HEIs should adapt to the changing socio-economical changes and the student needs. This translates in identifying and using the best possible technologies in delivering quality and sustainable learning experiences.

Technology transfer is usually associated with copyright, patenting and licensing. There are opportunities for further collaborations among HEIs and the corporate world that could prove beneficial. Furthermore, University Technological parks and research centers could become entities that will bridge gaps between academic and corporate learning.

The growth of experiential learning options available to students, provides an option for further use of technology as well as the basis for developing professional skills. In an inter-connected world, distance learning offers educational and emotional experiences to learners. Executive and corporate education is another area that has benefited from the use of new technologies in the higher education industry. This sector has benefited from collaborations among HEIs and corporations for the benefit of learners.

Based on each person's unique abilities and competencies, the team within which the person is related to, will more easily develop competencies and skills. HEIs may well cater to develop such competencies, capabilities and skills that may be further employed by students in effective communication and teamwork and in social interaction.

CONCLUSION

Innovation in science and technology within higher education, may develop healthy competition with the innovative tools that it employs. Innovative tools consist of the promotional communication strategies of the institutions that are online advertised on their website and on social media. It also illustrates that the institution does not stay stable, it develops and goes with the current wave adopting new information and communication technologies. In that way, a virtuous circle is created since innovation attracts more attendants such as alumni, postgraduates, undergraduates, funding from big companies. Learning processes in physical environments can be harmonically used with online learning processes.

KEY TERMS AND DEFINITIONS

Executive Education: Education that aims at mainly providing non-credit education. This can be tailored to the needs of people working in the business environment and/ or aim to acquire further knowledge on a specific topic of interest.

Experiential Learning: Learning that takes place through hands-on experience.

Innovation in Higher Education: Use of innovative tools and methods by academic institutions.

New Technologies as a Marketing Tool: Innovative web based devices that can promote products and services within a specific framework.

Social Skills: Competencies to interact successfully with other people. Innovative communication technologies may contribute to this successful interaction.

Teamwork: Cooperation among a group of people by employing skills and competencies in order to accomplish a specific goal.

Technology Transfer: The process of transferring skills, technologies, competencies that have been created based on research and can be further utilized to create products and services for the use of many people.

Experiences of Implementing a Large-Scale Blended, Flipped Learning Project

Hazel Owen

Ethos Consultancy NZ, New Zealand

Nicola Dunham

Massey University, New Zealand

INTRODUCTION

Many schools, tertiary institutions, and other organisations are involved in the design of eLearning experiences, but, it is questionable whether the investment results in more engaged, knowledgeable, skilled learners (Poulova, & Simonova, 2015). Two key prevalences that influence effectiveness have been identified. The first is a set of beliefs, often unquestioned (Byham, 2007), that tend to shape overall expectations of what eLearning experiences might comprise. The second is a tendency to embark on large-scale, ‘monolithic’ eLearning developments (JISC, 2005). The term monolithic, in the context of software and eLearning, refers to developments that do not have separate components and are part of the same architecture (Tanenbaum, 2014). It is sometimes used as a pejorative term, referring to the fact that it is slow, if not impossible, to change anything after rollout without starting over again. Therefore, monolithic deliverables in education are problematic, in part because there is an up-front cost before any learning value is realised.

In this chapter, experiences of implementing a large blended-learning project at a tertiary institution in Aotearoa New Zealand are discussed. Tertiary education in Aotearoa New Zealand covers all post-secondary education (from certificate to PhD level) and is akin to the term Higher Education in other countries. The project (instigated at the beginning of 2012) was based on a phased rollout, with each subsequent

stage being informed by the ones before. Steps included needs analysis, design, development, prototyping, refinement, and deployment. The discussion focuses on personal reflections on the two initial phases of the project from three different perspectives. The overall aim is to share contextualised experiences, to add to the knowledge base on blended learning, and to provide some general, practical recommendations.

BACKGROUND

This section provides an overview of the context and scope of the project. The project was driven by initiatives to improve student learning experiences; enhance interdisciplinary education; introduce a common semester; and develop a new Masters level course and a Professional Doctorate (Owen, & Dunham, 2015). One caveat was that technology itself would do nothing to enhance learning and teaching; as such, sound pedagogical theory and eLearning principles (Weidert, 2012) needed to be driving forces. It was also recognised that the change would impact professional identity, and therefore require flexible management and responsive processes.

The three participants in the study (two of whom are also the authors of this chapter) worked closely together on the project, and have been involved for many years with facilitation, teacher professional development (PD), and curriculum design. One has been working within the eLearn-

ing field for almost 15 years. As participants they undertook key roles, and were able to provide perspectives on, and insights into, motivations, challenges, and PD needs.

The remit was to design, develop and implement a blended, flipped approach to interdisciplinary learning. As such, the project team worked with subject matter experts, writers, and curriculum editors to redesign curricula. The design included discovery-orientated tasks that learners were encouraged to engage with prior to attending regular facilitated synchronous sessions (either face-to-face or in a webinar). Design and facilitation were flipped to focus on the learners and encourage them to find and create their own resources, as well as engage with, guide and 'teach' their peers. Prior learning could be extended by facilitators and peers - especially important in courses where students may already be working and have years of experience. Interdisciplinary learning was integrated by encouraging learners to explore from multiple practice and discipline perspectives.

As part of the change process a new centre was established in May 2014. The centre ensured a reasonable amount of autonomy, so that while the 'what' was directed by the executive team, the 'how' was more for the project team to decide. As such, they were able to, for example, trial an agile collaborative approach to writing and development. The course writing and design process, built around iterative cycles, shifted from being the sole responsibility of individual lecturers to become a team-based, collaborative and transparent approach at all levels: from writing and design, to the facilitation of the courses (Figure 1).

LITERATURE REVIEW

Two aspects are key to the design approach and implementation, and these are explored before moving into a more detailed discussion of the associated research and results.

Iterative Approach and Agility

Russell (2006, para. 16) advises that "because e-learning projects are... chaotic, it is usually best to implement a project management approach that is built for chaos." A release-based, iterative approach can address some issues that arise from chaos, especially when underpinned by an agile framework. In the context of the project referred to in this chapter, a brief comparison of the iterative approach with an alternative monolithic approach, illustrates some of the benefits (Russell, 2006):

- The iterative approach enabled a project plan to be developed for each two- to three-month phase, compared with a monolithic approach where a project plan would have been necessary for the whole initiative, which could extend over several years.
- The project started small, and had increased transparency and resiliency (Haikin, 2013).
- Each iteration was designed, developed, tested, changed in response to feedback, and rolled-out to learners. In contrast, a monolithic approach would have required the design, development, testing, and roll-out of the whole thing to learners. The iterative approach enabled learning activities and experiences to be evaluated (Hudson, 2012) and changed as needed.
- The institution was able to undertake iterations for as long as either 1) budgeted and signed off for; or 2) built into the ongoing design of programmes such that courses remained current.
- There was an ability to respond to issues as they arose and this saved "resources and, ultimately, help[ed] deliver a successful project on time and within budget" (Rouse, 2011, para. 2).

Identity and Openness to Change

In simplistic terms, there are two types of change in education: cyclical and transformative. Cyclical

Figure 1. The writing, design and development process

change is ongoing, and institutions initiate it or respond to it as it happens, occasionally returning to the stage they were at previously (Toynbee, 1947). In contrast, transformative change is ho-

listic, disruptive, often uncomfortable, happens at all levels, and is irreversible (Wallace, 1970). In other words, once an institution has undergone transformative change it will not be able to return

to the way it was before. Transformative change, however, requires the people and culture within an institution to work with ambiguity, as well as to question their beliefs, professional identity and practice. Not everyone will want to be part of this type of change, especially when it re-frames existing notions of formal learning. As such, there can be an uneasy dichotomy where the current culture of an institution sits alongside innovations happening within it.

Mindset theory has been associated with organisational culture and change, with a fixed mindset being associated with a culture of genius, and a growth mindset being associated with a culture of development (Murphy & Dweck, 2010). A genius culture endorses the belief that intelligence is fixed, while a development-culture views intelligence as malleable and expandable. When a person possesses a fixed mindset, they:

- Tend to avoid challenges,
- Deflect feedback,
- Withdraw when they meet obstacles,
- See little point in putting in extra effort, and
- Are threatened by other people's success (Dweck, 2012).

In contrast, people who possess a growth mindset tend:

- To see failure as part of the process (Dweck, 2000),
- Actively seek challenges, perceiving them as something that, if they work hard work to overcome them, will help them to grow intellectually (Dweck, 2012),
- See feedback as something that will help them develop, and celebrate the success of other people.

However, Dweck's research suggests that people can, with support, shift from a fixed to a growth mindset (Dweck, 2012).

Transformative change can be associated with learning goals and growth mindsets, whereas a genius culture may value performance goals over learning goals (Murphy & Dweck, 2010). Cyclical change, with the risk of returning to previous ways of doing things, aligns with a culture of genius in which maintaining standards may impede the undertaking of challenges. These concepts have implications for the type of support offered to people within a project, as well as recognition that some practitioners may not be change-ready, and will need time to move into a space where they feel comfortable and confident with taking risks.

METHOD

This research draws on principles of phenomenology to explore 'lived experience' from the perspectives of people involved (Welman & Kruger, 1999), through the use of reflective accounts. Reflective accounts are an established means of conducting practitioner-focused research within the field of education (Campbell, McNamara & Gilroy, 2004), and are a means by which lived experiences can be attributed meaning (Schutz, 1997). The researchers do not claim that they are in the possession of 'truth' (Griffiths, 2009), but rather they are approaching this experience of knowing as one of potential transformation within the context of organisational change.

The three participants in the project, from a stance of identity and integrity (Palmer, 2007), incorporated the principle of personal situated inquiry into writing reflective accounts about their experiences (Samaras, 2011). The researchers then carried out an independent cross-analysis of each other's reflections. A synthesis of codes and themes from the three reflections were collated and form the heart of this chapter. This approach of independent and cross-analysis is in keeping with aforementioned principles of personal situated inquiry and is a transparent and systematic research process (Samaras, 2011). To preserve

some semblance of anonymity, quotes used in the discussion of the analysed reflections are attributed to participant 1, 2, or 3.

DISCUSSION OF EMERGENT THEMES

The following section is organised around themes emerging from analysis of the reflective accounts, with verbatim quotes incorporated into the discussion. Themes include:

- Working with dilemmas and ambiguity,
- Shifting identities and practices, and
- Iterative and agile approaches.

Working with Dilemmas and Ambiguity

The need for strong support, decision-making and leadership to appropriately and consistently manage dilemmas plays a significant part in an effective change process. Within this project, however, Participant 2 identified “an uneasy dichotomy between the support... from senior management, and the sense of urgency to see a return on investment,” resulting in the participant feeling “torn between ensuring a really rigorous quality assurance and piloting process, and meeting the expectations to deliver.” Participant 3 also observed that “if a new teaching and learning paradigm is introduced at a time when an organisation is undergoing major financial restructuring ... the potential... benefits to learners are in danger of being overshadowed.” Indeed one source of ambiguity was that broader institutional interests could both support, and undermine, the project.

It was also realised that current institutional systems and structures were not compatible with the new approaches, creating issues with day-to-day logistics. For instance, there were “gaps in existing orientation systems ... [which] left both students and the teaching team exposed”

(Participant 1). These concerns led to the team being mindful about ensuring the ideology and philosophy behind developing the blended, flipped approach was not lost in the everyday and the administrative.

While institutional support for the project was evidenced through ongoing resourcing there was a “gap in understanding between how much resource ... [had been originally] estimated for an initiative of this scope, and how much was actually required” (Participant 2). This resulted in a “sense of a job done not quite well enough; of not quite enough support offered,” which resulted in writers “writing under incredible pressure, of curriculum editors who [wanted] ... to develop professional relationships further, and of eLearning designers and builders working flat out” (Participant 2). Furthermore, Participant 3 identified that “staffing was not conducive to the level of support the literature was telling me would ensure the best outcome for student experience and success.” The institution responded, but slowly, not having the nimbleness to change processes and support in response to rapidly emerging requirements.

Time was seen as both a positive and a negative. At a project-management level, complex interdependencies, including resourcing, constantly impacted the iterative process. For example, an iteration would be timeboxed, but then because “the process of recruiting and seconding writers was painfully slow... timelines ... slipped, and then slipped again” (Participant 2). The three participants, also, were eager to meet the demands of the project, but needed to balance their personal lives and ongoing professional aspirations (two, for example, were studying for their doctorates). On the other hand, the iterative approach provided time for all project staff to understand writing for the blended, flipped environment, and to acclimatise to the high degree of collaboration and transparency. Also, the courses could be designed and written such that they were ‘good enough’, knowing that improvements could be made in future iterations, informed by feedback and experience.

Shifting Identities and Practices

On a practical level the attitudes and professional practices of the educators involved needed to shift (Bonk & Cummings, 1998). The underpinning principles and approaches used in the project had led to re-framing roles for lecturers (to collaborative writers and facilitators), eLearning designers (to mentors and guides), and students (to active, self-defining learners). The writing approach, for instance, required what Participant 1 described as “a meeting of minds.” For this to work well, there was a “need for a team to be built not only on skills and experience, but also on relationships, complementary... beliefs, and an openness to true collaboration” (Participant 2). No longer were academics working in isolation; rather teams of writers and developers liaised closely with multiple stakeholders - “a less than usual practice within academic course development” (Participant 3). However, although providing benefits, the approach did create, for some project staff, challenges around identity - especially when roles were ill-defined.

Project team members worked hard to ensure effective professional development support, and to recognise opportunities. Participant 2, for instance, explained that writers were immersed in the process “while being mentored and guided by a Curriculum Editor.” Writers and facilitators supported each other in a more collegial and ‘open’ space, in ways that were responsive to the evolving nature of the project. However, “there were some writers... who felt quite vulnerable and found the collaborative writing process threatening” (Participant 2). Further complications became apparent when content was the focus of an existing course, whereby the writer often tended toward “giving students ... information (knowledge) as opposed to ... engaging them more with the process of learning” (Participant 1). As such, the the whole team had to strive to keep “co-constructivism at the heart of what we are designing and not slipping back into didactic habits” (Participant

1). Part of the issue was that the re-framed roles challenged existing understandings of what an academic practitioner is and does. Participant 3 explained that “On the one hand I wanted to teach responsively and reach out to Māori students to engage them in relation-based, face-to-face learning On the other hand I had an obligation to the methodological approach... being trialled,” and found herself “struggling to ... know the new terrain being created, as a teacher.”

Working collaboratively was defined not only by skills and knowledge, but relationships that supported educators to embrace change. Exposing raw thinking to peers as part of the writing process was enlightening, inspiring and unnerving. For some, for instance, it encouraged them to question existing perceptions of self as ‘knower’ of content and pedagogy, and explore their own knowledge and mindsets. In addition, working collaboratively and transparently meant that the academic silos could not continue to function.

Considering these factors in light of Dweck’s mindsets:

- Participant 1 identified herself as “a bit of a change-magnet” who was ready to “be part of something bigger.”
- Participant 2 felt “intrigued” by the proposed changes.
- Participant 3 was more ambivalent and saw the project as something where “the risk is unknown and the stakes are quite high.”

While all three acknowledged multiple challenges, it appeared that their willingness to take risks, along with a well-developed resilience, and a creative attitude to problem-solving (all features of a growth mindset), helped them relish change to the point where Participant 1 shared: “I was really feeling a sense of flying, of freshness and a chance to give things a go.” Without having growth mindset dispositions it is unlikely that these participants would have become, and stayed, involved in the project.

Iterative and Agile Approaches

The iterative approach had both benefits and drawbacks. One of the major benefits was that, in Phase 1, only initial requirements were required. These were used to specify, design and develop a prototype course, which stakeholders evaluated, and their feedback was applied to the other three initial courses required in Phase 1. In turn, findings from the roll-out of the four courses to learners helped the team identify and avoid the replication of errors; something that proved “invaluable... as we moved into Phase 2 and 3” (Participant 2). On a more micro-scale, course writers found the opportunity to edit a course multiple times was positive, although limited experience made it difficult for some to know what ‘good enough’ was and when to stop, thereby creating slippage. Such benefits were constrained by a wider context. As alluded to earlier, the project centre was “struggling within the larger overall organisation’s existing structures and formal procedures” (Participant 2). The structures and procedures were essential for the overall institution, but sometimes undermined “the dynamic capabilities required for an iterative cycle of rapid innovation” (Participant 2).

In spite of the challenges, toward the second-half of semester 1, 2014, it was observed that “students...were showing signs of engaging and succeeding. The final ... triumph ... [was] our innovative integrated assessment. At last we could see the learning that had occurred and just what the students could achieve” (Participant 1). In addition, Participant 2 felt “that we were developing courses that [were] ... accessible,... culturally responsive, [and]... ‘look and feel’ different to the usual blended learning experience.”

In relation to the project itself the benefits have been numerous; the three participants appeared to have sufficient confidence to embrace ambiguity, and to continue to draw on strategies to address challenges. However, the long-term impact on project personnel remains a concern and questions have been raised about sustainability: while “there

is still a great enthusiasm for the project ... there are a lot of tired faces” (Participant 2).

SOLUTIONS AND RECOMMENDATIONS

In this section key learnings have been identified and offered as recommendations for organisations implementing eLearning projects, which include:

- Roles and responsibilities,
- Project management,
- Ownership and shared understandings, and
- Review processes.

Roles and Responsibilities

When involved in a period of change, a project using an iterative approach provides time for practitioners - and departments - to shift and develop their identity, as well as to build liaisons and shared understandings. A complementary aspect is the opportunity for a project team to identify risks around roles and responsibilities early and put in place robust mitigations. Associated considerations are:

- Agreements are made around roles and responsibilities within the wider institution.
- There is widespread understanding that innovative projects include ‘doing things differently’.
- Institutional processes are unlikely to be responsive enough to keep up with rapid change.
- Every project team will have members with different levels of expertise and experience; parity of input and output is important for a well-functioning team (Owen & Allardice, 2014).

Innovation does not happen without tension and indeed tension provides some of the energy that

drives innovation. In part it is fostered by critical engagement which, by its very nature, causes dissonance. So, being innovative is not about removing the tensions, but about being aware and mindful of them, thus creating an environment where people can thrive and grow without being overwhelmed or over-stressed - which can lead to a reversion to original ways of being and doing.

Project Management

Project management is an essential aspect of an iterative, large-scale eLearning project - and something that is sometimes overlooked or not appropriately resourced. A project manager will, amongst other things:

- Organise, manage and allocate resources (including writers / subject matter experts, curriculum editors, and eLearning designer / developers),
- Set up timelines for development, and timebox each iteration,
- Help an institution complete an iteration within the agreed scope, while also meeting quality requirements,
- Identify risks and issues, as well as possible mitigations,
- Provide for PD, time release, and other incentives,
- Analyse results of evaluations to inform and modify a project on an ongoing basis, and
- Communicate progress regularly to all stakeholders.

‘Ownership’ and Shared Understandings

Ownership is achieved in supportive groups where there is a good level of consensus around underpinning principles and approaches. Where shared understandings are not present a coherent approach to project implementation is not possible. Construction of meaning may “result

from individual critical reflection but ideas are generated and knowledge constructed through the collaborative and confirmatory process of sustained dialogue within a critical community” (Garrison & Archer, 2000, p. 91). As such, it is recommended that project participants should:

- Be actively involved from the inception of a project,
- Have input into choosing underpinning educational philosophies,
- Identify their own professional needs, as well as those of their learners (Yoo, Huang, & Wenhao, 2013),
- Contribute to the design and prototype/pilot, and
- Take time and space to develop professionally until they are ready to be involved.

Review Processes

Finally, it is recommended that a longitudinal review study be conducted during the implementation of an eLearning project (Owen & Allardice, 2014). The review needs to be systematic, iterative, meaningful and non-intrusive. Results can inform following iterations around effective practices, recognise changing needs and technologies, and evaluate the efficacy of the approach. Comparative studies of effective practices and academic research are also desirable. Students must feel a sense of ownership, and this can be encouraged through fostering a tight-knit learning community that actively seeks and applies their feedback (Owen & Allardice, 2014).

FUTURE RESEARCH DIRECTIONS

The flipped blended model ensured that students were actively involved in their learning as co-constructors of knowledge, as opposed to passive recipients. Early results indicate that students were engaged, aware of metacognitive strategies they were employing, and were enjoying the flexibility

the blended, flipped design enabled. However, as yet the evidence is mainly anecdotal, and student success and retention will be the focus of a future research study.

CONCLUSION

This chapter is not about an end point; rather it is a snapshot of initial steps. The aim over the next phases is to continue to “emphasize the little things” (Flyvbjerg, 2001, p. 133), thereby providing an ongoing account of the minutiae of day-to-day undertakings that are part of implementing a flipped, blended, interdisciplinary initiative in one “remote corner of the universe” (Flyvbjerg, 1998, p. 1). It is hoped that the level of detail might help identify nuances that may otherwise be missed, and yet that can fundamentally influence the success, or otherwise, of an initiative.

Shifting mindsets has been a major part of the experience for the project participants. The highly collaborative and iterative approach enabled them to challenge their perspectives of intelligence - both their own and their prospective learners, as they worked through the process of developing and facilitating a design where active learning experiences were the driver, and content took a back seat. The change process required a willingness and ability to move out of predefined roles into a dynamic environment where previous ways of working were overridden, and highly responsive alternatives adopted.

The shift to a collaborative, transparent, agile approach to eLearning development has not been simple. The transformative change experienced was uncomfortable, disruptive, happened at all levels, was irreversible, and caused dissonance. The authors suggested that innovation does not happen without tension and indeed it was tension that provided some of the energy that drove this innovation. So, being innovative was not about removing tensions, but about being aware and mindful, while providing an environment that

encouraged people to move from fixed to growth mindsets. It was about thriving and surviving; about feeling inspired, supported, and valued.

KEY TERMS AND DEFINITIONS

Agile: A flexible approach, where the focus is small-scale but functioning releases of a course / product. These releases are evaluated, and improvements integrated.

Blended Learning: Learning facilitated through a variety of modes of delivery, styles of learning, and transparent communication (on- and off-campus).

Change Management: Approaches, strategies and frameworks used to support the people-side of change to achieve an institution's required outcomes.

Flipped Learning: Shifting the focus of learning from the facilitator to the learner, partly by reversing what happens inside and outside of a formal learning session.

Iterative: Approach for arriving at desired result by repeating a cycle of processes.

Mindset: Set of attitudes held by someone, which in the context of this chapter relate specifically to intelligence and learning.

Project Management: Methodical approach to planning and guiding a project.

BACKGROUND

Defining Flipped Learning

BL is a combination of face-to-face delivery and online delivery of learning materials and activities (Osguthorpe & Graham, 2003). Teachers interested in BL are searching for ways to make use of the rapidly expanding number of online easily-accessible learning resources. The increase in the use of technology to connect learning environments inside and outside the classroom has recently accelerated due to two developments in educational resources: the free online access to university courses via software, e.g. iTunes U, and websites such as Coursera (<https://www.coursera.org/>); and the sophisticated communication capability of mobile devices such as smart phones and tablet computers.

A promising response to these developments is the FL approach to the BL teaching methodology (Stuntz, 2013; Bishop & Verleger, 2013) which reverses the conventional patterns of classroom learning. Hamdan, McKnight, McKnight, & Arfstrom (2013) define the differences between FL practices and distance learning and BL courses by explaining that if the use of computers and online content does not alter conventional patterns of direct instruction in teacher-centered classrooms, it is not FL. In FL courses students are provided with outside-of-class online learning materials conventionally presented in class by the teacher. Classroom time is used for students to seek advice from the teacher and to help each other as they complete tasks which are usually done as outside-of-class assignments (Lage, Platt, & Treglia, 2000).

DOI: 10.4018/978-1-5225-2255-3.ch334

Yarbro, Arfstrom, McKnight, & McKnight (2014) define FL as “a pedagogical approach in which direct instruction moves from the group learning space to the individual learning space, and the resulting group space is transformed into a dynamic, interactive learning environment where the educator guides students as they apply concepts and engage creatively in the subject matter” (p.5). FL facilitates active collaborative learning during class time by allowing teachers to respond to individual differences in the comprehension of course content. At the same time students are given opportunities to find learning methods and materials that suit their own learning styles (Lage, Platt, & Treglia, 2000) through engagement in project-based learning activities which include small-group discussion and problem-solving activities. Thus, FL has the greatest chance of success with small-sized classes that make peer interaction manageable and allow teachers to take on a coaching role.

The rationale of FL, the expectations for student participation in their own learning, and the role of the teacher should be explained and demonstrated to students in the early stages of a course.

Flipped Learning for Foreign Language Learning

Recent studies offer encouragement that an FL approach to language teaching should be further investigated through a classroom-based action research methodology. Stuntz (2013) reported that students in a FL CALL EFL course needed instruction and practice in the use of communication and study media such as Gmail and Google Docs to complete outside-of-class assignments. Improvements in these skills allowed for effective use of class time to discuss outside-of-class learning tasks with both their peers and the instructor. The collaboration resulted in higher quality task products. A Learning Management System platform can guide students through the outside-of-class online learning tasks (Sung, 2015). Student satisfaction can enhance motivation when FL

course learning task products are shared with the class and with members of a broader community via YouTube® (Leis, Cooke, & Tohei, 2015). Interactive communication with an international community can be achieved by engaging EFL students in video conferences with students in other countries (Kuhn & Hoffstaedter, 2015). Access to authentic language-use opportunities of this nature in FL courses may decrease in-class performance anxiety among students (Egbert, Herman, & Chang, 2014).

As teachers and students learn how to apply the on-going developments in educational infrastructure, they will discover effective combinations of what can be done best outside, and inside, of classrooms. The potential of FL rests on an assumption that students will use the learning materials before class, so that classroom time can be devoted to problem-solving tasks and analytical examinations of the learning materials. It is crucially important to sustain student engagement in outside-of-class online learning tasks.

Sustaining Student Engagement in Flipped Learning

As with any innovation in education initial mistrust must be overcome. In FL the doubts center on the online element of learning, especially if the outside-of-class work-load increases, and if the students believe that learning is best in face-to-face lecture courses. Moreover, online learning components can be perceived as risky by parents, teachers, and learners if there appears to be no immediate and significant improvement in achievement (Hess, 2006; Dixon, Osment, & Panke, 2009). Parsons (2011) reports that a feeling of being overwhelmed at having to adapt to a new learning environment and discover new roles without proper support can result in a poor understanding of FL course purposes. Thus, students may not stay involved long enough in the outside-of-class course components until a critical mass of satisfaction and achievement is reached.

Although Internet communication is a ubiquitous feature of the lives of today's learners, it does not mean that they can employ it successfully for learning. A loss of motivation due to unfamiliarity with their learning tools can be compounded when students feel overwhelmed cognitively by the array of resources (Barker, 2006). Vaughan (2007) found that students who felt overwhelmed by the technology and by an overabundance of resources did not develop such successful self-regulated learning (SRL) skills. Thus, if learners do not already have SRL skills, there may be a consequent early loss in motivation soon after an FL course begins. Although there is some conflicting evidence whether FL can foster the development of SRL skills (Cho, Demei, & Laffey, 2010; Ishikawa et al., 2015), SRL competence may be a necessary prerequisite for success in FL courses, as is the case in Distance Learning (Andrade & Bunker, 2009; Zhao & Johnson, 2012). Furthermore, Ng, Seeshing Yeung, & Yuk Hung Hon (2006) found that in the case of foreign language learners, those with a higher level of language proficiency, and confidence, could handle unfamiliar learning styles better than lower level learners. In addition, lower level learners may not enjoy the multiple FL interaction channels, and so, feedback may be less effective.

Hartnett, George, & Dron (2010) found that learners felt that online interaction for collaborative work was less productive than meeting face-to-face in terms of saving time and receiving more effective feedback. Online mentoring may be a solution. Azevedo, Moos, Greene, Winters, & Cromley (2008) found that in a hyper-media environment, students demonstrated better performance when they received their goals from a teacher rather than from online learning tools. Thus, a combination of e-mentoring and in-class advice from other students and a teacher may be important consideration in FL course design.

The Transformation to Flipped Learning

Conventional in-class EFL methodology typically consists of three phases: input, intake, and output activities. Students are exposed to comprehensive input of an English text in order that they may have an opportunity to learn about a language feature that is new to them. If they understand the new feature of the language and it becomes part of their language knowledge, intake has occurred (Ishikawa, Kondo, & Smith, 2010). After engaging in learning tasks which are intended to allow intake to occur, students conduct output activities to practice using the new language feature. At the end of the class, the teacher usually assigns homework as an individual outside-of-class learning task to reinforce the in-class learning. The grading of the homework assignment by the teacher confirms whether the intended teaching aims have been achieved.

In an FL course, as the input component, students work on learning tasks online outside of class. The teacher supports students' learning by e-mentoring communication, such as by the sending of timely needs-based messages to the students via social networking systems. E-mentoring can be defined as similar to traditional mentoring but accomplished through online communication.

In class, after the students reflect on their outside-of-class activities, they collaborate in small groups on intake and output learning tasks which the teacher facilitates within a collaborative learning environment. At the end of the class the students reflect on what they did in class. E-mentoring may establish a computer mediated, mutually beneficial, relationship between a mentor and a learner when the mentor advises and encourages the learner by modeling effective learning behavior in ways that are boundary-less, egalitarian, and qualitatively different from traditional face-to-face mentoring (Bierema & Merriam, 2002). E-mentoring can be used to support

SRL skill development by developing a strong sense of self-efficacy, and by building relationships with peers and teachers that contribute to effective learning (Norton, 2005; Chang, 2004; McKenzie & Ozkan, 2006).

The following conceptual diagram was organized according to the principles of the phases of the continuous academic learning cycle described in the work of Schunk & Zimmerman (1998) which was further developed by Cleary & Zimmerman (2004). The three phases of the cycle make up a process which facilitates the transfer of a sense of ownership of the learning from the teacher to the student. The first phase of the cycle is *forethought*, intended to be self-motivating, in which students analyze their tasks, set goals, and plan strategies to achieve their goals. The second phase is termed *performance control*. In this phase self-instruction is based on self-determined focuses of attention in order to plan learning task strategies. Self-observation of the processes and products of learning are intended to achieve a sense of self

control. The third phase, intended to restart the cycle is *self-reflection* in which students make self-judgments by evaluating their own learning and attributing the various results to consequences of their own needs and their own actions (Kondo et al., 2012). The aim of the third phase is to achieve a feeling of self-satisfaction that may lead to the development of adaptability as the students learn how to deal with unexpected, as well as expected, consequences of their learning. Figure 1 shows a conceptual diagram of the transformation of a conventional in-class lesson to an FL lesson.

A Definition of Flipped Learning

FL, in this description of the transformation process from conventional EFL methodology to a flipped learning approach, is a form of BL in which students complete EFL course TOEIC study materials outside of class online and receive personalized problem-solving guidance from the teacher in class.

Figure 1. Conceptual diagram of the transformation of a conventional in-class lesson to flipped learning

The Flipped Learning Course Design

In order to help students improve their TOEIC scores, an FL course was designed and implemented at a university in Japan. Tasks were presented in the course in which classroom teaching methods and online delivery of course content and instruction were combined.

Each session had three phases: 1) pre-class online completion of TOEIC course materials; 2) individualized problem-solving instruction in class; and 3) post-class online completion of self-assessment and reflection learning tasks. Outside of class, the www-based courseware, ATR CALL BRIX was used.

In class the students first discussed their weaknesses and strengths in English listening and reading skills with their peers. After the students learned test-taking strategies to improve their TOEIC scores from the instructor, they completed quizzes given by the instructor and checked with their peers whether they had overcome their weaknesses. In an outside-of-class post-class session, the students carried out reviews of the in-class lesson with the learning materials contained in the ATR CALL BRIX online learning management system. Figure 2 outlines the learning tasks in one session of an FL lesson.

ATR CALL BRIX

The www-based courseware, ATR CALL BRIX (<http://www.atr-lt.jp/products/brix/index.html>),

includes a learning management system (LMS). The LMS provides a variety of learning materials designed to prepare students for the TOEIC Test. Seven different functions were featured on the LMS: 1) study logs, 2) feedback on the achievement rates of student-set goals, 3) records of the frequency of the use of the materials, 4) a record of time spent on learning, 5) a continuous update of the students' average score on the TOEIC learning tasks, 6) an evaluation of students' weak points and advice for further learning, and 7) students' rankings in comparison with other students in the course (Ishikawa et al., 2014).

E-Mentoring: A Self-Evaluation System

A student self-evaluation system was integrated in the courseware that was intended to contribute to the development of students' SRL attitudes, skills and behavior, and thus, sustain student use of the learning materials. The system combined, as part of the outside-of-class course routine, e-mentoring with weekly self-evaluations by means of the LMS. The students in the experimental FL group were placed in three sections—high, mid and low (mean $\pm$ 0.5SD) – according to their scores of the TOEIC Test which the students took at the beginning of the course. An e-mentoring team of one teacher and a teaching assistant sent different needs-based messages of advice and encouragement to the students every week by means of a social networking system called LINE (<http://line>).

Figure 2. Procedure of activities in one session

me/en/). The messages were varied according to how successfully the students had completed the learning materials (Ishikawa et al., 2016).

VALIDATION OF THE STUDY

Participants

551 first-year students who enrolled in a TOEIC course participated in this study. 348 students were included in an experimental FL group and 203 students in a control group. The two groups were placed in separate classes.

Methods

For the FL experimental group, the course design described above, was implemented. In the control group, students followed the same course design but they used neither the web-based courseware, ATR CALL BRIX, nor the self-evaluation system. All their learning materials were paper-based. Pre- and post-TOEIC Tests were conducted before the course started and at the end of the second semester in January 2015. The experimental-group students took the TOEIC Test again at the end of the first semester in July 2014, in addition to the

pre- and post-TOEIC Test. Students in the FL group completed course evaluations at the end of the second semester.

Results and Discussion

TOEIC Testing

The increase in TOEIC scores between the mid and low sections of the FL experimental group and the control group was compared. The high section of the experimental group was excluded because the average scores for the pre-test in both experimental and control groups should be comparable. The increase of the scores in the experimental group was 151.38 and that in the control group was 54.04. The scores of the post-test in the two groups was compared and there was a significant difference ($p < .001$; $d = .56$) as is shown in Table 1.

Furthermore, students who took the TOEIC Test in April and July, 2014, and January, 2015 in each of the three sections of the FL experimental group improved their TOEIC scores by approximately 150 points from April, 2014 to January, 2015 (see Table 2). This is an indication the students in all three sections of the FL course sustained their study efforts throughout the full

Table 1. Results of pre- and post-TOEIC testing

	Experimental			Control			<i>t</i>	<i>d</i>
	<i>Mean</i>	<i>SD</i>	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>n</i>

Low	286.12	43.65	409.58	79.17	443.50	96.35	107

academic year at a level at least equal to that of the students in the conventional class since they used the same basic TOEIC learning materials.

Post Course Student Evaluation

The course evaluation for the experimental FL group conducted at the end of the second semester consisted of 20 questions (see Table 3). Four open-ended questions asked about the students' feelings about the course and the in-class activities, about the problems that they may have had in using the LMS learning materials, and particularly about the messages sent by the e-mentor team. A 4-point Likert Scale was used for the responses in order to adequately allow for the expression of a range of students' feelings about the course. The ratings of 2 and 1, respectively, corresponded to disagree, and strongly disagree; and the ratings of 3 and 4, respectively, corresponded to agree, and strongly agree. The rate of reliability of the twenty 4-point Likert Scale questions was high ($\alpha = .91$).

The FL students were convinced that the in-class learning tasks were useful in strengthening their TOEIC listening and reading skills. Typical comments were similar to the following student's response: "I enjoyed the in-class activities. I was

able to learn TOEIC test-taking strategies which improved my TOEIC scores."

As for the use of the outside-of-class learning materials in the LMS of the ATR CALL BRIX, the majority of the students felt that the learning tasks improved their TOEIC scores. However, some of the students did not feel that they were able to solve problems that they had faced while using the LMS learning materials: "I don't know why but I often had problems in using the learning materials." There were other negative reactions to the use of the LMS: for example, looking at the display screen hurt their eyes; and they found problems in using the learning materials at home.

The advice of the e-mentor team seemed to be a key factor in the students' sustained FL study efforts. In response to the open-ended question many students commented, "The encouragement from the teacher helped me continue with the outside-of-class activities. I really think so." Some of the students believed that the FL approach to study suited their own learning styles.

The results of the evaluations showed that the FL students sustained their study efforts both in the in-class activities and in the online outside-of-class learning tasks. Furthermore, there was a suggestion that the use of a FL approach in EFL teaching would be sustainable.

Table 3. Results of the questions in the FL students' course evaluation

	Item	Mean	SD
1	The in-class activities helped improve my total TOEIC score.	3.26	0.79
2	The in-class activities helped improve my TOEIC listening score.	3.24	0.81

FUTURE RESEARCH DIRECTIONS

Until recently, it was assumed that university students would mainly use laptop and desktop computers to access online learning materials at school and elsewhere. However, the use of a variety of mobile devices with online access, such as mobile phones and tablet computers, is now the preferred means of information gathering and student-to-student online communication in some university communities in Japan (Mynavi, 2015). Thus, further research should be conducted to investigate the most productive, and sustainable, uses of mobile devices for FL.

CONCLUSION

The FL approach to TOEIC test preparation, described in this chapter, helped improve students' scores on the TOEIC Test in comparison with the gains made by students in a conventional course. SRL skills at the mid- and low-English proficiency levels appeared to be a factor in sustaining students' efforts which resulted in greater gains in TOEIC scores. According to the review of BL literature referred to previously, students at mid and low English-proficiency levels may not only have weaker SRL skills, but they also cannot usually be expected to develop SRL skills through the use of online learning materials. Thus, the design and implementation of this FL course may be a useful guide to the design of other FL courses.

FL rests on an assumption that students will use learning task materials before class, so that classroom time can be devoted to interaction between students and their teacher that will support the outside-of-class study through collaborative problem-solving tasks and analytical examinations of the learning materials. Thus, the findings reported in this chapter are important.

KEY TERMS AND DEFINITIONS

Blended Learning: Blended learning in this chapter is defined as a combination of in-class activities with outside-of-class activities.

E-Mentoring: E-Mentoring may establish a computer mediated, mutually beneficial relationship between a mentor and a learner if the mentor advises and encourages the learner by modeling effective learning behavior in ways that are boundary-less, egalitarian, and qualitatively different from traditional face-to-face mentoring.

Flipped Learning: Flipped learning in this chapter is defined as a form of blended learning in which students complete the EFL course TOEIC study materials outside of class online and receive personalized problem-solving guidance from the teacher in class.

Self-Regulated Learning: Self-regulated learning is a set of proactive processes that students use to acquire academic skills, such as setting goals, selecting and deploying strategies, and self-monitoring one's own effectiveness.

A Framework for Profiling Prospective Students in Higher Education

Santhosh Kumar Lakkaraju

Deb Tech
Dakota State University, USA

Shuyuan Deng
Dakota State University, USA

INTRODUCTION

Prospective student acquisition is a prominent issue in higher education marketing. Noel-Levitz (2012) estimated that higher education institutions are losing as high as 75% of the prospects after receiving an inquiry. Another study reported that 80% of the students who decide to apply to a program were influenced by the post-inquiry communications they had received from the higher education institutions (Aarinen, 2012). This chapter attempts to study the underlying concepts from literature and design a framework to extract prospective student profiles and further extend a discussion on how these profiles can be used to address the prospect engagement.

BACKGROUND

In general, the consumer buying decision-making process consists of five different phases that drive potential shoppers throughout their purchase process. Kotler & Armstrong (2006) defined the five consumer buying decision-making phases as Need Recognition, Information Search, Evaluation of Alternatives, Making a Decision and Post Purchase Behavior. The higher education institutions tackle these consumer buying decision-making phases through the four phases of the admission funnel. The admission funnel primarily consists of the

awareness, inquiry, and application and admissions phases as shown in Figure 1.

The awareness phase involves different marketing techniques the institutions rely on to reach out to prospects. The awareness phase will address the need recognition and information search phases by providing relevant information on the institutional websites. During the inquiry phase, a prospect tends to look for potential information on the institutional website and makes an inquiry by filling out the inquiry form. The institution responds to those inquiries by sending out different kinds of communications to prospects. These communications play a critical role in helping prospects to make a decision to apply or not.

The inquiry phase primarily targets the evaluation of alternatives and making a decision phases.

In the application phase, the institutions receive an application from the prospect. The cycle ends with the admission phase where the prospect would receive a decision on the application from the Institution.

To better market themselves and increase their student population, higher education institutions are employing different techniques like online (or) pay per click marketing and print media to increase their local and global presence and, social media to increase their social presence as well as brand awareness. Because of this exponentially growing educational market and varying prospective student behavior, institutions are receiving a

Figure 1. Admission Funnel

large number of inquiries from prospects about a specific program than the actual enrollments into that program (Hemsley-Brown & Oplatka, 2006; Moogan, 2011; Morris, 2009).

Earlier studies investigated several key decision-making variables of a prospective student (Aarinen, 2012; Moogan, Baron, & Harris, 1999; Moogan, 2011; Schäfer & Kummer, 2013), and some studies investigated the current student demographics to predict prospective student enrollment (Desjardins, 2002; Goenner & Pauls, 2006; Tareef & Balas, 2009). Other research studies developed predictive models using prospective student geo-demographic information collected through the online inquiries and estimated the prospective student enrollment rates (Goenner & Pauls, 2006; Michael, 1990; Morris, 2009). However, most of the online inquiries that educational institutions receive are incomplete, which will eventually provide incorrect predictions (Dupaul, 2010).

Moogan (2011) articulated that due to the lack of awareness about the kind of information a prospective student might be interested in receiving during the decision-making period, many educational institutions are losing potential prospects. The prospects tend to look for information before and after making the inquiry. The information accessed before making an inquiry is considered

as pre-inquiry navigational behavior and the information accessed after making an inquiry is considered as post-inquiry navigational behavior.

In general, profiling can be defined as the recording and analysis of an individual's psychological and behavioral characteristics (Nicoletti, Schiaffino, & Godoy, 2013). Building prospective student profiles is a complex task, as prospects do not usually give away explicit information about their interests (Catherine Bounsaythip, 2001; Srivastava, Cooley, Deshpande, & Tan, 2000). Therefore, the prospective student interests must be mined implicitly from the web server logs. Constructing accurate and comprehensive customer profiles play a key role in target marketing and enhanced customer engagement (Adomavicius & Alexander, 2001; Crossley, Kings, & Scott, 2003; Nicoletti et al., 2013).

Constructing prospective student profiles begin with collecting the prospect's information from various sources like online inquiry forms, campus visits, information brochures, educational fairs and job fairs. From a prospective student perspective, the general educational purchase process can be described in four phases: general interest in higher education, research for a specific institution or program of interest, decision to apply for one or more schools and finally, making a decision to enroll in a specific program (Goenner & Pauls, 2006).

From a higher education institution perspective, the general educational sales and marketing funnel or the admission funnel shown in Figure 1 has four distinct stages: awareness, inquiries, applications and admissions (Kotler & Armstrong, 2006; Nicolescu, 2009; Noel-Levitz, 2012; Oplatka & Hemsley-Brown, 2004). A prospect browses through different pages within an institutional website leaving trails of navigational information that can be mined from the server logs. This navigational behavior will be used in the extraction of prospective student profiles. Profiling prospective students based on their priorities would help in channeling a prospect to specific communications and increase satisfaction (Bhate & Pasha, 2014). It is proposed that prospective students' priorities can be identified from the prospect's existing browsing activities using pre-inquiry and post-inquiry navigational information.

Desjardins (2002) implemented an analytical strategy to assist higher education institutional marketing efforts. Desjardins (2002) applied a conceptual model based on the human capital theory that considered variables like current student demographics, admitted years, enrolled programs, application forms etc. Desjardins (2002) attempted to fit a statistical model by considering the historical data of admitted students and tried to accurately predict enrollment. Following this work, Goenner & Pauls (2006) proposed a model to predict the enrollment decisions of prospective students based on their inquiries. Goenner & Pauls (2006) combined the prospective student demographics with US census data and proposed that the prospects from a specific geographic region behave in a specific pattern.

Goenner & Pauls (2006) & Desjardins (2002) predicted a prospect's enrollment decision and then suggested specific marketing communications channels for prospective students, current students, and alumni. Moogan, (2011) specified that customer specific information in the communications chain might improve the retention rates as well as the brand image of the institution.

He also articulated that the prospects are to be considered as valuable customers and complete effective communications are to be exchanged between the prospects. Such relationship needs to be established from the inquiry phase till his/her graduation from the program. According to Moogan (2011), most of the existing research was conducted before or in the early stages of the evolution of online marketing and do not reflect the current marketing technologies to match the information needs of the students.

This chapter attempts to generate a dialog of ongoing higher education marketing efforts and the contribute to the institutional advancement by making use of analytics.

MAIN FOCUS OF THE CHAPTER

This chapter focuses on a comprehensive review of existing higher education marketing literature and extracts a theoretical model. This theoretical model is further used in formulating the framework to profile prospective students.

THEORETICAL MODEL

The theoretical model is derived from the works of Desjardins, (2002); Goenner & Pauls, (2006); Hossler & Gallagher, (1987); Michael, (1990). Hossler & Gallagher, (1987) articulated that a student's choice of an institution depends on the predisposition of pursuing higher education, selecting schools of interest and apply to the institutions based on choice. Desjardins, (2002) articulated that higher education institutions tend to make use of economic models and business intelligence models in promoting marketing methods and reporting. Goenner & Pauls, (2006) developed a model that made use of the prospect demographic and financial information extracted from the applications and predicted the enrollment numbers. Michael, (1990) emphasized on different factors that influence the prospects behavior from choosing one university over the other.

Figure 2. Theoretical model derived from literature

The theoretical model shown in Figure2 illustrates the interdependency of the student choice in researching for potential schools in the market as well as the institutional efforts in capturing the prospective student's attention through their communications. This prospective student information can be further mined and used to personalize and customize the communications that have a direct impact on persuading prospective students. According to Oinas-kukkonen & Harjumaa, (2009), information tailored to the potential needs of a prospect or to the interests and personality of a prospect will be more persuasive. From the theoretical model, it is clear that student choice, institutional efforts and the communications that a prospect receives will persuade a prospective student's decision-making behavior.

PROSPECT DECISION-MAKING FACTORS

There are different factors that contribute to a prospect's decision in selecting a graduate program in an educational institution. Extensive research has been done in identifying different decision-making factors of a prospective student (Moogan et al., 1999; Moogan, 2011; Sheppard, 2013).

Moogan (2011) analyzed the decision-making criteria of new undergraduates enrolling in terms of marketing techniques employed throughout the decision-making period.

Sheppard (2013) investigated different factors that influence prospective students in decision-making and the aggregated analysis is provided in the following table. A survey instrument was developed by Sheppard, (2013) that addressed six different aspects namely: external influences, education and career goals, information gathering, university financial aid, program characteristics and university characteristics. Noel-Levitz (2012) conducted a survey to extract different factors that influence graduate student college choice. The results varied from online versus regional prospects. Different key prospective student decision-making factors identified from the literature are articulated in Table 1.

The decision-making factors in table 1 have provided this study a foundational reference. The following section provides an overview on the translation of the decision-making factors into prospect profiles based on their contextual relevance.

Table 1. Key prospective student decision-making factors

Author	Decision-Making Factors
(Aarinen, 2012; María Cubillo, Sánchez, & Cerviño, 2006)	International recognition, suitability, reputation, specialization, quality of the program, courses, future earnings, future job or career opportunities, admission requirements, language requirements, educational facilities, fee, financial aid, City image, institution size.
(Moogan, 2011)	Teaching quality, course content, university reputation, research quality, faculty reputation, accreditation, facilities, student life, career prospects, entry dates, open day, the cost of living, accommodation, friends and family opinion, teacher's opinion, distance from home.
(Morris, 2009)	Electronic catalog, electronic application, inquiry forms, financial aid forms, course registration, email correspondence are some of the key decision-making factors
(Sheppard, 2013)	Program availability, career goals, income, credentials, personal development, flexibility of class scheduling, location, cost of attendance, reputation

FRAMEWORK

Different decision-making factors identified from literature (Aarinen, 2012; María Cubillo et al., 2006; Moogan, 2011; Morris, 2009; Sheppard, 2013) spoke about the factors consisting of specific contextual information. These decision-making factors are categorized into five different prospect profiles namely: price, program, future employment, institutional image, and the environment. This categorization is done based on their contextual relevance as shown in the framework below in Figure 3.

From Table 1, the factors cost of attendance, financial aid availability and cost of living provide information related to price.

The factors availability of the program, online, part-time, distance, location, and flexibility of class schedules provide program related information to the prospects.

The factors career advancements and goals, course content, future jobs, future earnings and on-campus employment provide a prospect with future employment related information.

The factors institutional Reputation, teaching quality, faculty expertise and reputation, research quality, quality of the program and institutional provide the prospect with an institutional image related information.

The factors technology use, educational facilities, and student life provide the prospect with the environment related information.

Institutions provide specific information addressing the decision-making factors on their websites. Based on these prospect profiles the web pages within the institutional website are categorized into different content profiles. Pages that address a specific context are tagged with prospect profile names based on the context as followed: Price, Program, Future employment, Institutional Image and Environment.

IMPORTANCE OF PROSPECT PROFILES

This section provides an overview of crucial decision-making factors and their importance in this research. Extensive study has been conducted on identifying different influential factors that impact a prospect's choice of an institution or program. Ivy & Naude, (2004) introduced a 5P model where the 5P's stands for product, price, place, promotion and people. In a detailed sense, the product represents the program a prospect is going to invest his money on; price represents the cost of the program, place deals with the environment or location of the institution, promotion targets the future employment and people deals with the student life and institutional image. Filip, (2012) proposed a 7P model and included processes and physical facilities to the existing 5Ps. Processes refer to the way the enrollment system, teaching and learning habits, social and sports activities are established within the institution. Physical facili-

Figure 3. Framework representing the prospect profiles

ties address the institutional equipment, technical infrastructure etc.

Although it is up to an institution to target specific factors in reaching out to prospects, a research study conducted by Noel-Levitz, (2012) clearly articulated that cost, financial aid, academic reputation, institutional size, future employment and campus location are crucial prospect decision-making factors. Higher education institutions usually structure their program-related information targeting these specific decision-making factors on their websites.

SOLUTIONS AND FUTURE RESEARCH DIRECTIONS

This framework can be used along with analytical models to optimize prospect communications, provide timely and relevant information to the prospects. This framework can act as a foundational reference for accurately profile prospects. The prospect profiling framework is designed by relying on the existing literature.

With the increasing use of social media by the prospects, institutions are trying to expand their reputation and social presence by investing valuable resources in social media. There might be some unknown variables that may act as decision-making factors for prospects in choosing one institution over the other. In the future, this study can be extended in extracting prospect preferences and decision-making factors on institutional social profiles.

CONCLUSION

This chapter provided an overview of the existing higher education marketing literature and extracted different prospect decision-making factors. These decision-making factors are further translated into prospect profiles based on their contextual relevance. The prospect profiles from the framework can be used in the institutional marketing strategies to optimize the prospect communications, identify prospect behavior over the institutional website and optimize the web pages accordingly.

ACKNOWLEDGMENT

We would like to sincerely thank all the reviewers for their inputs and suggestions. The chapter is intended for audience from higher education marketing. Different profiles extracted from the literature intend to bring a conceptual awareness in the marketing departments to find different ways to target their prospects and address their needs. The chapter has been modified in accordance with the reviewers suggestions and we also appreciate the reviewers for the time spent on this chapter.

KEY TERMS AND DEFINITIONS

Analytics: The discovery, interpretation and communication of meaningful patterns in data.

Conversion: A *marketing* tactic that encourages a customer to take a specific action. In electronic commerce, *conversion marketing* is the phrase used to often describe the act of *converting* a customer who browses your site to a paying customer.

E-Marketing: Also known as internet marketing, web marketing, or digital marketing. They refer to advertising and marketing efforts that make use of web and email to drive traffic and make sales.

Profiling: The recording and analysis of a person's psychological and behavioral characteristics, so as to assess or predict their capabilities in a certain sphere or to assist in identifying a particular subgroup of people.

Prospects: A person regarded as likely to become a potential customer.

Importance of Information Literacy

Lidia Sanchez-Ruiz

Beatriz Blanco

University of Cantabria, Spain

INTRODUCTION

During the last decade an educational change has taken place in many European countries. The European Union has promoted several reforms in the university education system in order to create a common European Higher Education Area (EHEA).

The changes introduced aimed to adopt a comparable degree system (Sanchez-Ruiz, Pérez-Pérez, Blanco-Rojo, & Serrano-Bedia, 2013), being one of their main objectives the adoption of a competency-based education system.

Among the wide range of competences that students may acquire, the relevance of information literacy has increased during the last decade as we are said to live in an information society.

But, what does information society mean? As Webster (2006) said this concept has been extensively studied from different perspectives (technological, economic, occupational, spatial and cultural). Whatever the perspective, *they all share the conviction that quantitative changes in information are bringing into being a qualitatively new sort of social system, the information society* (Webster, 2006).

In this new scenario, information becomes a key aspect in everybody's professional and personal lives. Thus, a new concept appears: information literacy. *It entails the learning of the skills, competences, knowledge and value to access, use and communicate information in any of its forms, in order to produce competent professionals trained in the routines of identifying, evaluating and recording information sources appropriately and*

with the knowledge to process and produce their own information (Pinto, Doucet, & Fernández-Ramos, 2007).

Despite information literacy is not always considered a core competence, many organisations require information literacy skills on their job offers (Klusek & Bornstein, 2008). Therefore, every university student should acquire and develop information literacy skills during their undergraduate studies. For instance, among the whole range of information literacy skills, students should: be aware of the goals for which they are going to use information, know how to use available technologies to organise and store information, be able to assimilate the key information of documents or know how to synthesise and represent essential information properly (Pinto et al., 2007).

Taking this into consideration, as a first step, students should be aware of the relevance of information literacy skills. Once they are aware of its importance, they are able to improve and develop them. Thus, the aim of this study is to analyse whether university students are aware of the importance of information literacy. Additionally, we will analyse whether their awareness varies or not after attending an information training course.

Once the objectives of this study have been stated, the structure of the rest of the paper will be as follows. First, in the next section (Background) the basic concepts of this study (European Higher Education Area, Information literacy and the IL-HUMASS survey) are explained. After this, the following section includes information about the methodology used and, after that, the results obtained in this study are presented. Next, some

recommendations based in the results are made. Finally, future research suggestions are presented together with the conclusion of this research.

BACKGROUND

The European Higher Education Area

The European Higher Education Area (EHEA) is aimed to adopt a comparable degree system from a common system of credits (ECTS) based on two main levels –undergraduate and postgraduate– harmonizing its duration and combining the balance between basic education, cross-cutting skills, specific knowledge and discipline skills, and professional competence (Sanchez-Ruiz, Pérez-Pérez, Blanco-Rojo, & Serrano-Bedia, 2013).

Although the intention of convergence had already been expressed in the Sorbonne Declaration (1998), it was due to the Bologna Declaration that the process was accelerated. Specifically, the main objectives of the Bologna Declaration were (ANECA 2005, pp.27-28):

- Adoption of a model of degrees based on two levels: undergraduate and graduate.
- Creation of the European Credit Transfer System (ECTS).
- Establishment of a comprehensible and comparable degree system.
- Promoting mobility in Europe.
- Improving the quality of institutions.
- Promoting education and training throughout the whole career.
- Adopting a competence-based education system.

According to an extensive review of literature, companies require four characteristics from their employees: content of study, social skills, methodological skills and participation skills (Marzo-Navarro, Pedraja-Iglesias, & Rivera-Torres 2009). Before the implementation of the EHEA, universities primarily focused on the first one, the content

of study. However, later the development of other skills has been encouraged from the university.

Competence is understood as “the combination of knowledge, skills (intellectual, manual, social...), attitudes and values that will enable the graduate to successfully tackle the problem solving or intervention in an issue in an academic, professional or social context” (MEC 2006).

Two types of competences may be distinguished: specific and generic. Generic competences are those attributes that a graduate must have regardless of their degree; while specific competences are defined as observable behaviours that are directly related to the use of concepts, theories and skills of the degree (Martinez-Caro, & Cegarra-Navarro 2012, p.10).

There is a wide range of competences that students are supposed to acquire during their degrees (organising, solving, managing...). As above-stated, depending on the field of study, specific competences vary. However, generic competences are common to all the degrees. Among them, this study is focused in the information literacy competence that will be described in the following section.

Information Literacy

Although the concept of information literacy come into use in 1974, it has achieved its current popularity due to a proliferation of information available (Gradstein, 2002). Due to this fact, the concept of information literacy has been widely studied along literature from different perspectives and fields (Zabel, 2004).

Among all the existing definitions, the American Library Association definition has become widely accepted (Bherens, 1994). According to it (American Library Association, 1989), in order to *be information literate, a person must be able to recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information. Ultimately, information literate people are those who have learned how to learn. They know how to learn because they*

know how knowledge is organized, how to find information, and how to use information in such a way that others can learn from them. They are people prepared for lifelong learning, because they can always find the information needed for any task or decision at hand.

Taking this definition into consideration, Rader (1991) defined the following characteristics of an information literate person “*To be information literate means to do the following:*

- Survive and be successful in an information/technology environment;
- Lead productive, healthy, and satisfying lives in a democratic society;
- Effectively deal with rapidly changing environments;
- Ensure a better future for the next generation;
- Find appropriate information for personal and professional problem solving; and
- Have writing and computer proficiencies.

Therefore, according to Rader (1991), information-literate people know how to be lifelong learners in an information society.

More recently, Weber and Johnston (2003) defined information literacy as the adoption of appropriate information behaviour to identify, through whatever channel or medium, information well fitted to information needs, leading to wise and ethical use of information in society. Similarly, Pinto (2010) defined information literacy as the set of literacies or competencies that an informed citizen needs in order to participate judiciously and actively in an information society.

Regardless of whatever definition, there is a sufficient consensus about the relevance of information literacy as an educational goal (Owusu-Ansah, E.K., 2004). In fact, Burnheim (1992) already defined information literacy as a core competence as it is needed to learn and develop other competences. Additionally, regarding the above-mentioned classification, information literacy could be described as a generic competence

due to, no matter the degree, every student should learn and develop it.

As a result of the relevance of the concept, this study is aimed, firstly, to analyse whether university students are aware of the importance of information literacy. And, secondly, we will analyse whether their awareness varies or not after attending an information training course.

The IL-HUMASS Questionnaire

Among literature, different measurement and self-assessment tools have been created in order to measure information literacy development. Among them, in this study the IL-HUMASS survey is going to be used. It is *a comprehensive and user-friendly survey containing an exhaustive set of variables related to information literacy for the specific target population of the higher education in the humanities and social sciences* (Pinto, 2010). The election of this survey is due to the fact that this tool was specifically developed to be used among Spanish and Portuguese university students (Pinto, 2010).

According to this survey, information literacy skills are divided in four main factors: information search, information evaluation, information processing, and information communication and dissemination. In Table 1, the complete list of items which integrate each of the five factors are included.

In order to fulfil the objective of this research, this survey was conducted among higher education students. Thus, as it can be seen in Table 2, the scope of this study is limited to the Autonomous Community of Cantabria (a region in the North of Spain). Specifically, this survey was conducted among First Year university students from the Business and Management degree who attended an information training course. Each student had to value in a Likert scale (1 to 9) whether they consider each of the skills included in the survey important or not for their professional future.

The survey was conducted in March 2015 when the information training course began, and

Table 1. IL-HUMASS survey (Pinto, 2010)

Competence	Abilities	Code
Information search	Using printed sources of information (books, papers,...)	B.1
	Entering and using automatic catalogues	B.2
	Consulting and using electronic sources of primary information (journals...)	B.3
	Using electronic sources of secondary information (databases...)	B.4
	Knowing the terminology of your subject	B.5
	Searching for and retrieving internet information (advanced searches, directories...)	B.6
	Using informal electronic sources of information (blogs, discussion lists, etc.)	B.7
	Knowing information-search strategies (descriptors, Boolean operators, etc.)	B.8
Information evaluation	Assessing the quality of information resources	E.1
	Recognizing the author's ideas within the text	E.2
	Knowing the typology of scientific information sources (thesis, proceedings, etc.)	E.3
	Determining whether an information resource is updated	E.4
	Knowing the most relevant authors and institutions within your subject area	E.5
Information processing	Schematizing and abstracting information	T.1
	Recognizing text structure	T.2
	Using database managers (Access, MySWL,...)	T.3
	Using bibliographic reference managers (Endnote, Reference Manager...)	T.4
	Handling statistical programs and spreadsheets (SPSS, Excel...)	T.5
	Installing computer programs	T.6
Information communication and dissemination	Communicating in public	C.1
	Communicating in other languages	C.2
	Writing a document (report, academic work...)	C.3
	Knowing the code of ethics in your academic/professional field	C.4
	Knowing the laws on the use of information and intellectual property	C.5
	Creating academic presentations (Powerpoint...)	C.6
	Disseminating information on the internet (web, blogs...)	C.7

Table 2. Research technical record

Characteristics	Survey
Population	First Year university students from the Business and Management degree (University of Cantabria)
Population size	21 students
Geographical scope	Autonomous Community of Cantabria (region in the North of Spain)
Unit of analysis	Student
Period	March 2015-June 2015

in May 2015 when the course finished. The course is about searching and processing information strategies. The main learning outcomes of this basic course were: knowing the basic structure of a text; knowing the basic information sources that are available to students (books, specialised databases...); knowing the existing referencing rules; knowing the basics of several tools for data processing (Excel spreadsheet, Word processor, Powerpoint, posters...).

Finally, 21 valid surveys were collected. It represents around 60% of the students who were enrolled in the course, but nearly 90% of those who

usually attended it. At this point, authors would like to highlight that Rasch Measurement Theory is able to obtain valid and reliable results from small samples so, sample size, is not a problem in this case.

After collecting the data, Rasch Measurement Theory was used for data treatment. Due to the use of this methodology is still not widespread, the next section explains the basis of this method.

RASCH MEASUREMENT THEORY

In the Social Sciences field and, specifically, in the Business and Management area, there are many realities that cannot be directly measured. Thus, measurement is usually done indirectly by measuring a group of items that, in theory, integrate the construct or reality that we are interested in. In those cases, it is very common to use Likert scales to value those items. The scores obtained from the Likert scales cannot be considered measurements due to they are ordinal scores and, in order to consider them a measurement they should have an additive structure, a characteristic that only interval variables have.

Rasch Measurement Theory, initially developed by George Rasch (1960), solves this problem by transforming ordinal variables into interval variables. Rasch Measurement Theory is based in three principles: unidimensionality (a construct is unidimensional when all the items are referred to the same construct or latent variable so they can be located in the same lineal construct with the subjects); invariance (the results are independent from the samples of subjects and items used); and additivity.

When it comes to transform the ordinal variables into interval variables, the Theory is based in the following statement: *“persons who are more able/more developed have a greater likelihood of correctly answering all the items in the observation schedule. And, easier items are more likely to be answered/reached correctly by all persons”* ((Rasch 1960) in (Bond & Fox 2007, p.28)).

Then, the mathematical model is derived from the logistic function that relates the increasing probability of response to all items with the persons' ability (Gonzalez Montesinos, 2008).

From this statement, a new concept is defined: distance. It is the difference between the ability of the person (β) and the difficulty of the item (δ). Three situations may happen depending on the result of this difference:

- Si $\beta - \delta > 0$: the probability of the subject answering correctly to the item is more than 50%
- Si $\beta - \delta < 0$: the probability of the subject answering correctly to the item is less than 50%
- Si $\beta - \delta = 0$: the probability of the subject answering correctly to the item equals 50%

The mathematical expression of the model is derived from this idea and it can be consulted in any of the handbooks about the methodology (see (Bond, Fox 2007; Alagumalai, Curtis, & Hnugi 2005; von Davier, & Carstensen, 2007)).

Among its many applications we highlight the following: analysis of the global feasibility and reliability of the construct; analysis of the individual feasibility and reliability of the items and subjects; unidimensionality analysis; questionnaire scale analysis; and ranking of the items and/or persons (Sanchez & Blanco, 2012).

With regard to the data treatment, several software packages are available (Facets, Winsteps...). In this study the 3.75 Winsteps software is used (Linacre, 2012a).

RESULTS: UNIVERSITY STUDENTS' PERSPECTIVE

Firstly, the construct information literacy was validated, this is, the dimensionality, validity and reliability of the measures were globally and individually checked

After having checked the reliability and validity conditions, the abilities which integrated each of the competences were ordered based on the importance given by students.

Figure 1 shows the results obtained in the first survey, that is, the survey conducted at the beginning of the course. The vertical line represents the construct and the units are expressed in logits (interval units).

The crosses in the left of the vertical line represent the students' positions. On the other side, the codes in the right represent the items position. In each side, the M represents the average measure, the S represents one time the standard deviation distance, and finally T represents two times the standard deviation distance.

In general, due to the fact that the average measure for students (1.41 logits) is higher than the position of the average measure for the items (0.00 logits), it could be concluded that students do not consider information abilities important. Specifically, the most important item, according to students' perceptions, is the item C.2 "Communicating in other languages". In the opposite side, the least important item is E.3. "Knowing the typology of scientific information sources (thesis, proceedings, etc.)".

Once the course was finished, the survey was conducted again. Results are shown in Figure 2, whose interpretation follows the same rules explained in Figure 1. Although the specific results will be stated later, it is interesting to highlight that, comparing the position of the average measures, students consider information abilities more important after the course than at the beginning of the course.

In order to clarify the results obtained in Figures 1 and 2, the classification of information abilities based on students' perceptions are summarised in Table 3. Thus the first and second columns describe the code and the name of the abilities; the third column describes the position of each ability according to students' perceptions at the beginning of the course

(Figure 1), being the most important ability the one at the bottom as it was above mentioned; equally, the fourth column refers to the position of each ability according to students' perceptions at the end of the course (Figure 2), again being the most important one the item located at the bottom; finally, the fifth column compares the results of the two previous columns. Thus, if the position of an item gets worse means that students considered the ability more important at the beginning than at the end of the course; whereas if the item goes better, students value better the ability after the course than at the beginning. As it can be seen, abilities have been ordered based on students' perceptions at the beginning of the course.

Figure 1. Results from the initial survey

Figure 2. Results from the final survey

SOLUTIONS AND RECOMMENDATIONS

The objectives of this study were:

1. Analyzing whether university students are aware of the importance of information literacy
2. Analysing whether their awareness varies after attending an information training course

According to results, students do not consider information abilities important. This can be concluded from Figure 1, due to fact that the average measure for students (1.41 logits) is higher than the position of the average measure for the items (0.00 logits). However, it must be highlighted students increased the importance given after the information training course, as the difference between the average measures is reduced (average measure for items: 0 logits; average measure for students: 0.44 logits).

Additionally to these results, this research offers a classification of information abilities based on students' perceptions. Thus, writing and oral communication skills (C.1, C.2 and C.3) are the most important ones for them, being their position stable before and after the course. On the other side, knowing the typology of scientific information sources (E.3) is one of the least important abilities, although its position improves after the course.

FUTURE RESEARCH DIRECTIONS

Despite this study has been rigorously developed, the authors are aware of some of its limitations. For instance, authors consider that the scope of the study should be increased. Thus, in the future, the survey could be conducted among university students from different degrees, not only for the business and management degree. In the long term, the study should be conducted among students

Table 3. Results: Abilities position in the initial and in the final survey

Code	Abilities	Position According to Initial Survey	Position According to Final Survey	Evolution
C.2	Communicating in other languages	1	2	Get worse
C.1	Communicating in public	2	3	Get worse
C.3	Writing a document (report, academic work...)	3	5	Get worse
T.5	Handling statistical programs and spreadsheets (SPSS, Excel...)	4	6	Get worse
T.1	Schematizing and abstracting information	5	10	Get worse
B.6	Searching for and retrieving internet information (advanced searches, directories...)	6	8	Get worse
C.6	Creating academic presentations (Powerpoint...)	7	1	Get better
B.3	Consulting and using electronic sources of primary information (journals...)	8	12	Get worse
T.3	Using database managers (Access, MySWL,...)	9	19	Get worse
E.1	Assessing the quality of information resources	10	11	Get worse
B.5	Knowing the terminology of your subject	11	20	Get worse
C.4	Knowing the code of ethics in your academic/ professional field	12	15	Get worse
E.2	Recognizing the author's ideas within the text	13	16	Get worse
E.4	Determining whether an information resource is updated	14	7	Get better
C.7	Disseminating information on the internet (web, blogs....)	15	14	Get better
C.5	Knowing the laws on the use of information and intellectual property	16	13	Get better
T.6	Installing computer programs	17	9	Get better
T.2	Recognizing text structure	19	18	Get better
B.4	Using electronic sources of secondary information (databases...)	20	4	Get better
B.2	Entering and using automatic catalogues	21	25	Get better
B.8	Knowing information-search strategies (descriptors, Boolean operators, etc.)	22	24	Get better
T.4	Using bibliographic reference managers (Endnote, Reference Manager...)	23	17	Get better
E.5	Knowing the most relevant authors and institutions within your subject area	24	22	Get better
B.7	Using informal electronic sources of information (blogs, discussion lists, etc.)	25	26	Get worse
B.1	Using printed sources of information (books, papers,...)	26	21	Get better
E.3	Knowing the typology of scientific information sources (thesis, proceedings, etc.)	27	23	Get better

from other universities, even from other countries. Thus, cultural differences could be identified and analysed.

It would be also rewarding to analyse whether there are differences among first year and final year students.

Additionally, it would be interesting to analyze the self-efficacy that each student considers they have in each of the information abilities. By doing this, better training courses could be designed as they would better fit students' needs.

CONCLUSION

The concept of information literacy has been widely studied, especially during the last decade. Therefore, along literature many authors highlight the need of developing information abilities and skills in order to become an information-literate citizen. Before analysing whether students have these information abilities, it seems appropriate to analyse whether they are aware of their importance. If students are not aware of the relevance of information competences, they are not going to work in order to improve them.

Taking this into consideration, this study analysed the importance given by university students to a complete list of information abilities, concluding that students are not enough aware of their importance.

It was also concluded that, thanks to the information training course, the students' awareness was increased. This result highlights the need of developing transversal information courses that complement the specific modules of each degree. As it was said before, information literacy is a generic competence needed in every degree to complement the specific training of each professional branch. Sometimes these transversal courses do not receive the attention they deserve and the focus is on the specific modules. However, as it was also highlighted information literacy is a core competence needed to develop other competences. Therefore, some information courses

should be designed and included during the first undergraduate levels. These courses should be aimed at offering students information tools and techniques so they can be more efficient when learning other topics.

Overall, the authors consider that this research offers new sights on information literacy as it evaluates the awareness of students regarding information abilities. Nonetheless, due to the limited scope of the study, this study could be defined as exploratory and it would be interesting to replicate it in other universities and/or countries.

KEY TERMS AND DEFINITIONS

Competence: The combination of knowledge, skills (intellectual, manual, social...), attitudes and values that will enable the graduate to successfully tackle the problem solving or intervention in an issue in an academic, professional or social context (MEC 2006).

EHEA: European Higher Education Area.

IL-HUMASS Questionnaire: Self-assessment tool created to measure information literacy development among university students.

Information Communication and Dissemination: One of the factors that integrate the information literacy competence. It is about being able of transferring (orally or written) all the information, including the use of digital media.

Information evaluation: One of the factors that integrate the information literacy competence. It is referred to the ability of analyzing whether a piece of information is reliable, update.

Information Literacy: It entails the learning of the skills, competences, knowledge and value to access, use and communicate information in any of its forms, in order to produce competent professionals trained in the routines of identifying, evaluating and recording information sources appropriately and with the knowledge to process and produce their own information (Pinto et al., 2007).

Information Processing: One of the factors that integrate the information literacy competence. It is about being able of properly treating the information. Not only is it about understanding and using it, but it is also about correctly citing and referencing the sources used.

Information Search: One of the factors that integrate the information literacy competence. It includes all the skills and knowledge needed to find reliable information: searching techniques, information source.

An Integrated Electronic IQA System for HEI

Teay Shawyun

King Saud University, Saudi Arabia

INTRODUCTION

Regardless of what academics believe or like, with the depletion of public funding and increased competition, the reality is that higher education institutions' (HEI) future is more business oriented potentially affecting educational quality (Haworth & Conrad, 1997, Bowden & Marton, 1998). This over-commercialization and internalization to achieve individual "economic" needs rather than meeting the public needs and concerns is an issue that affects strong and sustained academic performance excellence. Yin, *et al.* (2002) noted that the education policy needs to include economic viewpoints that highlighted the needs for the institution to change the internal educational structures and systems to meet different educational purposes and aspirations by identifying, procuring and allocating appropriate resources for inputs that enhances the efficiency of internal processes of the system and its sub-systems to meet the short-term and/or long-term education needs. Conti (2006) also emphasized the need of understanding the quality management from the systems perspective by extending the quality management concepts of economic transactions to social relations that ultimately creates value to the stakeholders.

HEIs have a responsibility to the society to develop the future societal human capital through its educational value that they propose to the stakeholders through its internal value creation processes. The central issue is what and how these internal processes are aligned to create this educational value proposed to the stakeholders.

BACKGROUND OF STUDY

External Quality Assurance (EQA) as represented by any accreditation requirements has been prescribed voluntarily or mandated where all HEIs subscribe to or are mandatorily coerced into (Wells, 2014). While EQA hypes the protection of stakeholders' values in learning outcomes and competencies, the accompanying and complementary Internal Quality Assurance (IQA) struggles to keep up with the pace of EQA progress and requirements (Kettunen, 2012). Systems and mechanisms in accomplishing and achievement EQA requirements falters or are sidetracked due to the mundane IQA with volumes of documents, reports, statistics and evidences requirements of quality measures of processes and results underlying education value (Prikulis, Raugvargers, & Rusakova, 2011).

In attempting to resolve this issue, this chapter explores the key components of quality, information and planning underpinning education excellence to align the integration of the 3 main IQA core systems of quality management (QM), information management (IM) and planning management (PM) as these encompass most aspects of the creation and delivery of the educational value of HEIs. The proposed integrated eIQA is strategically and tactically aligned top-down and bottom-up where quality management is aligned with planning management via information management leading to informed decisions affecting quality management at all levels of the institution, administrative units, colleges and programs. To illustrate these QM-IM-PM linkages via its key

integrated e-modules, a case study of a leading university in the Middle East demonstrates this strategic integrated eIQA system.

CONCEPTUALIZATION OF AN INTEGRATED eIQA IN HEI

Arcaro (1995) stated that “Quality is creating an environment where educators, parents, government officials, community representatives, and business leaders work together to provide students with the resources they need to meet current and future academic, business, and societal needs”. This would mean that comprehensive systems and mechanisms to enrich and enhance these quality environments, albeit an integrated one or hybrids (Marsh, 1995), are an imperative for improving education through quality management (Tribus, 1993). These policies and procedures include faculty and personnel selection, motivation, development, engagement and retention; learner entry, guidance and student service and support systems; management information systems; student assessment; management of developing, delivering and evaluating learning programs and resources; availability and allocation of financial, administrative and physical resources; governance & administration; planning, monitoring and management of all educational performance measurement and management. All these allude to the ISO 8402 definition of a quality management system (QMS) as “the organizational structure, processes, procedures and resources needed to implement quality management”.

Goldberg and Cole (2002) identified three levels of education quality management application as 1) the management processes of HEI; 2) teaching quality to students who are both customers and workers in the educational system; with 3) highest level of quality in learning to achieve the desired results. These meant that educators must question their core teaching and learning processes, teaching pedagogy & strategies, and assessment methods. They contended that the traditional “institutionalized rationale” be replaced

by a systemic quality approach as espoused by Deming (1994) that “a system is a network of interdependent components that work together to try to accomplish the aim of the system.” The change to a systems perspective where the change is more systemic, the more the institution embodies changes in behaviors, culture, and structure, strategies, philosophies, processes, people, systems and mechanisms, the more lasting the change will be which is in line with Deming’s seventh principle resemblance of Senge’s (2006) systems thinking.

These systemic and the systematic processes where activities interact to achieve defined goals resulting in the quality of the product and services, constituting the QMS, is defined by DTI (2015) as “A set of coordinated activities to direct and control an organization in order to continually improve the effectiveness and efficiency of its performance”. This QMS enables an institution to provide consistency and coherence in the interactions and integrations of all education activities and processes of the institution’s goals and objectives achievements of its policies and strategies. This begins with the identification of stakeholders’ (students & parents, faculty & staff, regulatory bodies & society) requirements resulting with their satisfaction at every transaction interface. The QMS can be visualized as a “wedge” that both clasps the improvements, innovations and achievements along the quality journey, and prevents good practices from slipping back. Rouse & Putterill (2003) identified the QMS performance triplet as: performance measures, performance analysis and performance evaluation that corresponds to Altman’s (1979) three component of evaluation, data analysis and performance measures underpinning the QMS architecture.

An effective and efficient integrated QMS supports strategic directions with tactical implementations meeting stakeholders’ requirements and expectations; bringing about efficient and effective educational processes to create and deliver on educational value; reducing wastages and lower costs through activity based costing of the educational costs in deliverance of education values; and ultimately increasing morale and

motivations to strive for performance excellence and morals towards conscientious education benefiting the students. Hence, designing and building the integrated QMS includes the QMS infrastructure, the philosophies, plans, processes, procedures, people, practices and its deployment with performance measured and assessed bringing about continuous improvements and informed decision making paving the way towards performance excellence. The crux is the focus of improvement efforts in a holistic systemic and systematic approach to education QM. On the electronic dimension, the UN advocated the EMIS (Electronic Management Information System) that sought for the synergy and integration in terms of eight main aspects or dimensions: needs of producers and users; data; information handling; storage of data; retrieval of data; data analysis; computer and manual procedures; networking among users. This includes the data warehouse, the data marts and BI (Business Intelligence) tools, and its mire of networks. Arbogast (2009)

advocated that the “QMS be electronic, linked, or related so that the piece parts can be analyzed; be dynamic, when change is required and capable of being analyzed and changed quickly; maintains history from a corrective action management perspective, and is a real-time managed system published electronically to the total organization that adds value and providing speed and agility on a long-term basis”.

This calls for great efforts to be dedicated to the rationalization and strengthening of existing structures and processes and to improvement in the coordination of information flows and organizational commitment and an investment in real time online applications and database systems. All activities in terms of IPOO (Inputs, Processes, Outputs and Outcomes) in the handling of educational management information together with their performance measure and indicators are to be placed and coordinated within the same EMIS framework from-all-to-all internal and external sources and stakeholders (Figure 1) that includes

Figure 1.

Adapted from: Villanueva, C.C., 2003, Education Management Information System (EMIS) and the formulation of Education For All (EFA) Plan of Action, 2002-2015, U N E S C O Almaty Cluster Office and the Ministry of Education of Tajikistan

an eDRMS (electronic Document and Records Management System) (Queensland Government, 2010).

The bottom line is that the QMS, and eDRMS must be integrated electronically into an efficient and effective HEI eMIS quality and planning system of which this paper aims to discuss and demonstrate through the case study.

CASE STUDY OF KSU ELECTRONIC INTEGRATION OF QMS-IMS-PMS

The case study of King Saud University (KSU), a ranking university and leading university in the Middle East, will be used as the main illustration of the integrated eIQA system. A key question for QM is what takes place in between the 5/7 years accreditation cycle to sustain planning and continuous improvements. This is addressed through internal audits and assessments in between the accreditation cycles to assure continuous improvements and innovations. This can be an annual or bi-annual exercise to provide for time for planning

of actions with evidence of implementation bringing to fruits these plans which are monitored and measured for performance.

To manage KSU's IQA, a 3 staged KSU-QMS approach was developed (Figure 2) comprising of:

Stage 1 Self-Study: This comprises the tedious and mundane documentation required for QM and accreditation, which is the bane of equating quality to just documentations. The electronic part of the Course Specifications (CS) & Course Reports (CR) and Field Experience Specifications (FES) & Field Experience Report (FER) done on a semester basis culminates in the annual Program Report (PR) based on the Program Specification (PS). All these supports the development of the program Self-Study Report (SSR) and Self Evaluation Study Report (SESR) required for accreditation.

Stage 2 Internal Audit and Assessment (IAA): The bi-annual monitoring cycle and IAA of the program are done by an independent internally appointed Board of Assessors

Figure 2. Three Stages of KSU Quality Management System

(BOA) before the programs go for their every 5/7 years mandatory national accreditation. The main monitoring normally takes place at the core of the educational processes which is represented by the colleges and their program offerings. Its aim is to ensure that the periods in between the accreditation cycle strengthen or sustain improvements.

Stage 3 Developmental Planning: The aim of eIQA is to ensure continuous improvements with evidence substantiating these improvements meeting the vision, mission and goals as committed to the stakeholders and as planned in the strategic plan of the college or programs. The recommendations of the accreditation and IAA exercises leading to action plans and projects planned for addressing these recommendations are the key link to the strategic plan as these will address all the QMS and accreditation criteria which are in line with the overall strategic plan. This will avoid redundant planning and inconsistencies or incoherence across the quality-planning duo. As such, the bi-annual monitoring process of the developmental planning is aimed at capturing and closing the quality feedback loop to ensure that the quality drive is maintained and sustained through continuous improvements and actions from one accreditation cycle to another.

All these 3 stages are supported by the SID (Statistics, Information and Documents) system component in the KSU Data warehouse (Figure 3) of the “ITQAN” System part of the eIQA. The imperative is a set of corresponding statistics, information or documents that supports the assessment that is evidence-based. Key evidences are needed to substantiate and support the accomplishment and achievement of quality actions that had been planned, implemented, monitored for accomplishment and measured for achievements with comparisons to the previous years and to the industry benchmark. The same logic applies to key performance indicators (KPI) which are based

on the statistics & data. In effect, the institution/ college/programs/administrative units need to set up a system or mechanism to collate and analyze the statistics and information.

H

KSU ITQAN SYSTEM OF THE INTEGRATED eIQA SYSTEM

Figure 4 shows the re-conceptualized and re-configured integration of sub-systems components working in tandem and holistically of the KSU eIQA. These interwoven parts show key data sources inputs from various systems of surveys, performance metrics, eRegister, MADAR-HR, finance, learning resources, facilities & infrastructure, research and community services into the SID data mart. All these are used by the faculty to create their CS & CR and FES & FER, program chairs to create their PS & PR, program quality committee to develop their SSR & SESR and the Internal Benchmarking, all of which feeds into the IAA and accreditation components. These will culminate in the recommendations of assessors and Quality Performance and Assessment Report (QPAR) which are input to the developmental planning component linking the strategic plan's action plans and projects. These leads to consistent and coherent planning based on quality management inputs via its integrated data marts in the DWH, electronic information networks culminating in informed decision making efficiencies and effectiveness.

The integrated eIQA (Figure 5) linking and supporting the QM-IM-PM dimensions in the ITQAN system are composed of the following modules:

- **eSurvey Module:** The minimum 7 surveys of Course Satisfaction / Student Experience / Program Satisfaction / Faculty & Staff Satisfaction / Alumni & Employment Market Satisfaction, conducted on a semester and annual basis measuring stake-

Figure 3. KSU Data Warehouse (DWH) in the ITQAN System

holders' satisfaction, are key data inputs to the performance metrics module.

- **ePerformance Metrics Module:** This module handles all computation, aggregation and compilations of the 17 Strategic KPIs and 56 QMS KPIs inclusive of the 33 NCAAA (National Commission of Academic Accreditation and Assessment) KPIs measuring planning and quality performance and benchmarked in the benchmarking module where internal & external benchmarks are compared.

- **eQMS-Accreditation Module:** The core of the eQMS's QM is based on the multifarious NCAAA forms and templates requirements to be uploaded online to the Accreditation Management System (AMS) of NCAAA. In addition, this is supported by Curriculum Mapping Module where the Student Learning Outcomes, the teaching methodologies and students' assessment are mapped according to Program Objectives and Courses & Program Learning Outcomes (CLO/PLO) within the CLO/PLO Matrix. These include the key

Figure 4. KSU eIQA (internal quality assurance) conceptual mapping

Figure 5. Integrated and Electronic conceptualization of KSU eIQA and its modules

modules used by all the colleges, programs and faculty members to manage their CS & CR, PS & PR, FES & FER and SSR & SESR which are monitored for performance in key dashboards aggregated from the course levels up to the institution level.

- **eKSU-BOA Module:** The computerization help lighten the loads of the BOA and the programs in the IAA exercises of the 350 undergraduate and post graduate programs by the BOA once every 2 and half years for each program that requires substantial time and efforts of performance analysis, identifying strengths and areas for improvements, site visits issues based on the hefty evidence needed of the programs audit and assessment.
- **ePerformances Scoring Module:** The performance of the programs is based on the Performance scoring system with integration into the QPAR.
- **ePlanning's:** two sub-modules of:
 - **Planning Module:** where the strategic plan of the university's vision, mission, goals, objectives are defined and cascaded to the colleges' & administrative units' vision, mission, goals, objectives for alignment and linkages with the program objectives and action planning and the 4 perspectives of the Balanced Scorecard (BSC) of the KSU's 9 objectives. This will result in action plans and projects linked to the quality action plans and objectives subscribing to the same goals and objectives.
 - **Monitoring and Mentoring Module:** where KSU assigns mentors to the colleges to support them in the PM-QM, while at the same time monitoring the progress of the planning and quality action plans' accomplishment and achievements.
- **eFaculty & eStudent Portfolios Module:** To avoid duplications of data entry to 4 different systems of research, faculty portfolio

and evaluation, promotion and "FAC" web page, all the common data pertaining to the faculty work, responsibilities and performance are entered through a singular portal in this module. These are then channeled to each of the 4 systems for their specific usage, and this will cut down on the same data entry and requirement of 4 different systems. The efaculty or eStudent portfolios have a key purpose of formative and summative assessment of the student and his/her performance (Thompson & Cobb-Reiley, 2003; Barrett, 2004) for personal reflection and learning management. They have benefits of the tracking and documentation of teaching and learning experiences; encouraging the reconnection between learning process and outputs & outcomes; institutionalizing collaboration, reflection, and discussion. The outcomes of the student assessment and performance are integrated and customized to individual student's needs and requirements. The aim is for each student to integrate his/her study, social and extra curricula and personal requirements to better customize his/her formative and summative academic, social and personal workspace and work life.

- **eSID Module:** This is the main data mart for data, information statistics, documents of the ITQAN application of the different modules described above supported by the KSU DWH and data marts for key applications utilization.

SAMPLES OF KEY MODULES SCREENSHOTS OF ITQAN APPLICATION

Basically, the dashboard is one of the most important feature in the ITQAN system used for performance monitoring allowing drill-downs from the highest levels of institution to the program levels. Since the two main ITQAN's nuclei are

QM-IM-PM, there are 3 main sets of dashboards of 1) eQMS-Accreditation; 2) ePerformance Metrics and 3) eDevelopmental Planning & BSC. The dashboard (Figure 6) shows the key category of the university/colleges/programs degree of accomplishment in %, of the key areas of accreditation/program/course managements of the selected college/program (Figure 7) down to the level of all courses in each program (Figure 8). This allows the college/program or central eIQa management unit to have oversight and overview of the performance of all the colleges down to the levels of the individual courses accomplishment of the key CS & CR (Figure 9); FES & FER and the PS & PR; and ultimately the SSR and SESR progress towards IAA & accreditation (Figure 10).

A required QM best practice and accreditation for the curriculum mapping (Figure 11) is the definition & design of PLOs (Figure 12) and CLOs, the mapping of the CLO to the PLO based on the program objectives in the PLO/CLO mapping matrix Figure 13. At the course level, the assessment methods for the CLO for each of the student is shown, all of which are reported

as part of the course student assessment rubric. There is also a facility for the assessment of all the students' performance in a course (Figure 14) leading to the reporting of the competency index for that course/student (Figure 15) and performance metrics (Figure 16).

IMPLICATIONS OF THE INTEGRATED eIQa QUALITY-INFORMATION-PLANNING SYSTEMS

In the development of the integrated eIQa, it is considered a complete business process redesign that combine separate education processes into a singular core value process (Ashworth, 1999; Childe *et al.*, 1994; CIM-OSA Committee, 1989) cutting across different owners and domains as opposed to fragmented collections of individuals and small scale systems (Tovey, 1991; Mason, 1993), with the output directed to the internal and external stakeholders based on their strategic needs and satisfactions (Temporal, 1990; Bolt, 1993; Burach *et al.*, 1997).

Figure 9. Course specifications and course reports dashboard

As noted by Franco-Santos *et al.*, (2007), the two key characteristics of a strategic performance management system (SPMS) of “performance measures” and “supporting infrastructure” and the 3 key processes of: “information provision”, “measure design and selection” and “data capture” were incorporated into the architectural design of the integrated eIQa linking the quality-information-planning dimensions (Teay, 2012). The integrated eIQa, part of a SPMS provides measures of performance, progress and opportunities to refine or improve on the “what, why and how” mechanisms.

FUTURE RESEARCH DIRECTIONS

While this chapter discusses a basic integrated eIQa infrastructure that supports the QM-IM-PM in any HEI, there are vast potentials in enhancing this key enabler in:

- Predictive modeling of the vast data to support education predictive analytics (AAEA, 2014 and Tagtow, 2014) and Institutional Research Intelligence (Djunaidi, 2012) that goes beyond the typical institutional research and SPMS dashboards for HEIs.

Figure 16. ePerformance metrics dashboard

- Linkages directly to the national EQA for simplifying and supplementing international accreditation agencies requirements which can be extracted and modified from the core institution's QM-IM-PM.
- Drill downs to the individual student performance management and support focused on a more student-centric approach, with potentials of linking to faculty performance evaluation and management based on its teaching-learning-research database in the system.
- Improved overall SPMS of the HEI, colleges, programs and stakeholders.

CONCLUSION

This paper and the illustrated case suggest that the fundamental “piece-meals” flaws that had

always been obstacles in effective application of ICT for HEIs' educational aims and mission could be reconciled by:

- Bringing about an integrative approach of the strategic and education management with IS/IT as the enabler for QM-IM-PM integration, that are aligned to bring about the convergence of 3 very different and potentially unrelated disciplines. This could be done through the expert knowledge of the champion or change agent who must have knowledge and skills of the strategic needs of the HEI, the operationalization of the technicalities of ICT and details of the tedious and overwhelming quality management and accreditation requirements.
- Moving from the macro organizational strategic needs to the micro level operational or functional processes requirement of a new mind-set that calls on the capability and capacity of all the individuals and the organization as one to move in the same strategic direction for holistic aligned accomplishments and achievements. The key factor is in the operationalization of the micro aspect of the macro overview that underlies the precarious of internal processes and the human capital re-engineering and re-discovery.
- Linking and integrating strategically and tactically the core value addition processes of teaching-learning-research to the QM-IM-PM trio with ICT as the supporting enablers through a set of strategic and operational plans that forms the integration and electronic triangularization of the quality-information-planning approach as expounded.

In conclusion, even-though this paper emphasized on the strategic integration of the quality-information-planning trilogy, this does not mean that other concepts and frameworks are irrelevant. On the contrary, as noted by Andersen *et al.*

(2006), the quality, information and planning management, or for that matter, all aspects of the HEIs' commitment of educational value to society must be approached from a holistic perspective through sets of appropriate plethora of tools & techniques, systems & mechanisms depending on the situational and/or institutional requirements meeting and going beyond stakeholders' needs.

KEY TERMS AND DEFINITIONS

eDRMS (electronic Document and Records Management System): This contains the secure and systematic management of unstructured or semi-structured data, statistics, information and documents; a reduction in redundancy and duplication of information; a reduced risk of not being able to retrieve information when required; improved security, thereby reducing the risk of unauthorized access; greater ability to discover and re-use information; better control of statistics, information, data & document versions; and a reduction in the response time for information requests. This includes institutional information and metadata management strategies, standards, policies and procedures, effective data management culture of understanding and appreciation of the value of making, keeping and managing full and accurate statistics, data, information and documents, standard operating procedures including roles and responsibilities and security models (Queensland Government, 2010).

eIQA (electronic IQA): A collation of modular sub-systems which act inter-dependently for educational outputs that cover inputs, processes, output & outcomes (IPOO) modules inter-linked through the data warehouse (DWH), its data marts and use of Business Intelligence (BI) tools for analysis and ad-hoc reporting in assuring educational quality and performance excellence.

eMIS (Electronic Management Information System): This is “an organized group of information and documentation services that collects, stores, processes analyzes and disseminates information for educational planning and management. It is (1) a collection of component parts that include inputs processes, outputs and feed backs that are integrated to achieve a specific objective; (2) a system for managing a large body of data and information that can be readily retrieved, processed, analyzed, and made available for use and dissemination; (3) a tool that uses systems theory and developments in computerization to create a comprehensive approach to management and use of vast quantities of information in the education system” (Villanueva, 2003).

IQMS (Integrated Quality Management System): This is an integration of the performance and quality management for 3 key education purposes of 1) Development Appraisal; 2) Performance Management; 3) Whole-School Evaluation (De Bruyn, et al., 2007; ELRC, 2003).

QMS (Quality Management System): A QMS is a documented set of policies and procedures that provide assurance to the customer of the product and service levels expected which is: systems-based; people-based; process-based with emphasis on prevention (FASSET, 2000) and continuous improvements in all spheres to ensure and sustain efficiencies and effectiveness of educational quality and value.

H

International Students in Online Courses

María Ángeles Rodríguez Manzanares

Memorial University of Newfoundland, Canada

INTRODUCTION

Postsecondary institutions are focusing their efforts on recruiting higher numbers of international students. At the same time, they are increasing opportunities for students in general to complete courses online. We find ourselves, therefore, “at the intersection of two trends in postsecondary education” (Rodríguez Manzanares, 2012, p. 1), that is, a growth in online learning (including online courses) and an increase in numbers of postsecondary international students. However, to date, few studies have been conducted specifically on international students learning in online courses (Murphy & Rodríguez Manzanares, 2014; Rodríguez Manzanares, 2012).

The present article focuses on the little research that has so far been conducted on international students in online courses. In order to allow for a focus on recent research, only reports of studies of international students in online courses published after 2000 were included. Some of them (e.g., Rodríguez Manzanares, 2012; Sadykova, 2014; Zhang & Kenny, 2010) related to research that has been reported on elsewhere (see Murphy & Rodríguez Manzanares, 2014; Sadykova, 2013; Zhang, 2007). In terms of the studies’ research paradigms, Sadykova’s study relied on mixed methods and Liu’s (2008) and Sheu’s (2005) survey research fit within a quantitative research paradigm, while the other studies included in this article fit within a qualitative research paradigm.

In the studies that were selected for inclusion, the international students which were the focus of research were taking or had completed online courses or programs. Not all of the studies’ participants were completing their programs entirely online, as there were participants in the

studies who were enrolled in on-campus courses at least for part of their studies (whether taking them concurrently with online courses or not).

Researchers have different perceptions of the meaning of some terms used to describe different learning environments, such as is the case with “online learning,” “distance learning,” and “e-Learning” (see Moore, Dickson-Deane, & Galyen, 2010). For the purpose of this article, the focus was on online courses and an online course was defined as one being fully delivered using online technologies, without any face-to-face components being part of its design. For this reason, only studies in which international students completed courses designed to be completed entirely online were considered. Excluded were studies (e.g., Chen, Bennett, & Maton, 2008; Wang, 2006) that referred to most of the instruction (such as a percentage of it) being online.

The term “international student” is used interchangeably with “foreign student” (Abdullah, Aziz, & Ibrahim, 2014) in some contexts, but, in other contexts, it is used to refer to a subset of international students, in the sense that foreign students would comprise those “who are not citizens of the countr[y in which they are learning], but may be long-term residents or were born in that country” (Organisation for Economic Cooperation and Development, 2014, p. 352). To avoid terminological confusion, for the purpose of this article only the term “international students” is used. They are defined as those “enrolled in a university in a foreign country, where they do not have permanent residence” (Mehtap-Smadi & Hashemipour, 2011, p. 418). In order to ensure that the focus of the studies included in the present article was on students who would in fact have been considered “international students” in

DOI: 10.4018/978-1-5225-2255-3.ch338

their institutions, only studies indicating in their title that research was conducted in relation to “international students,” using that specific term, were selected for inclusion.

BACKGROUND

The increasing numbers of postsecondary international students in different countries attest to the efforts that postsecondary institutions are currently placing on recruiting more international students. For example, in the United States, the number of international students grew 72% between 2000 and 2014 (Institute of International Education, 2014) and, in Canada, international student enrollment (including students both at the postsecondary and other levels of education) grew 84% between 2003 and 2013 (Canadian Bureau for International Education, 2015). In the period from 2000 to 2012, as reported by the Organisation for Economic Co-operation and Development (2014), “the number of foreign tertiary students enrolled worldwide more than doubled, with an average annual growth rate of almost 7%” (p. 343). As indicated in a British Council report, demand for international student places in Australia, Canada, New Zealand, the United Kingdom, and the United States alone is predicted to increase from one million places to approximately 2.6 million places by 2020 (Bohm et al., 2004).

Alongside the trend of increasing international student enrollments at the postsecondary level, another current trend in postsecondary settings relates to increasing online course offerings (Murphy & Rodríguez Manzanares, 2014; Rodríguez Manzanares, 2012). For example, the EDUCAUSE Center for Analysis and Research published results of a survey in 2014 (Dahlstrom & Bichsel, 2014) which showed that almost half of surveyed students (47% exactly) reported having taken a completely online course the previous year. Data were collected from more than 75,000 students in 213 institutions in the United States and 15 other countries.

The present article aims to contribute to understanding postsecondary international students’ learning in online courses by focusing on the little research that has so far been conducted on international students in that specific learning setting. The next section reviews some of the findings of the studies of international students in online courses that were selected for inclusion in the article, following the selection criteria outlined in the Introduction above.

STUDIES OF INTERNATIONAL STUDENTS IN ONLINE COURSES

Students’ Reasons for Learning Online

Some of the insights gained from the studies of international students in online courses related to students’ reasons for taking courses in that format. This information was sometimes elicited directly from students, for example by including survey items (e.g., Liu, 2008; Sheu, 2005) or interview questions (e.g., Rodríguez Manzanares, 2012) in the studies on why they enrolled in online courses.

The main reason reported for taking courses online was time flexibility (e.g., Liu, 2008; Sheu, 2005; Rodríguez Manzanares, 2012) and also place flexibility in addition to time flexibility (e.g., Sheu, 2005; Rodríguez Manzanares, 2012). In Liu’s survey research, international students indicated that they enrolled in online courses, among other reasons, because of their advisor’s recommendation and the opportunity to work at one’s own pace (as indicated by 63% and 45.7% of the surveyed students, respectively). In terms of other findings, more than half of the students disagreed that they had enrolled in an online course because it was less expensive than a face-to-face course. Almost half disagreed that they had enrolled in online courses because they could provide the same quality as face-to-face ones.

In Tan et al.’s (2010) study, which relied on in-depth interviews with graduate international

students, participants reported avoiding taking more than one online course at the same time or per semester because of the perceived language- and culture-related challenges of learning in these courses. Wang and Reeves (2007) indicated that, sometimes, as was the case with the international students in their study, there are courses that are required and are offered only online. Finally, Sheu's (2005) study identified a reason for enrolling in online courses related to the fact that the face-to-face version of the course that students wanted to take was full.

Asynchronous Online Learning: Advantages and Disadvantages

Some studies identified the advantages (as perceived by students) of asynchronous learning in online courses for international students. Some of these were highlighted in relation to the time independence afforded by online courses (e.g., Liu, 2008; Park, 2006; Rodríguez Manzanares, 2012). In Liu's research, 67.4% of participants responded "agree" or "strongly agree" in relation to a survey item regarding whether the schedules of their online courses were flexible. As explained in Park's study of Asian students, students can "control time, place, and pace in their learning" (p. 67) in online courses. The time delay which is characteristic of text-based asynchronous learning in particular was identified as an advantage for international students in online courses, especially for English as a Second Language (ESL) speakers. In Park's study and others (e.g., Rodríguez Manzanares, 2012; Tan et al., 2010), the benefits of learning asynchronously in online courses for ESL speakers were highlighted in relation to asynchronous online discussions. Park referred to students having the opportunity to "[have] more time to think and write for their discussions" (p. 69). Tan et al. reported on international students' positive perceptions that online courses "promoted writing with care for an audience, providing opportunity for editing and revising correspondence before posting it..." (p. 12). Rodríguez Manzanares

also reported on students being able to organise their thoughts in advance when crafting messages, work in their own time, and concentrate on writing accurately in English, such as by relying on online dictionaries.

In Rodríguez Manzanares' (2012) research, other advantages of asynchronous learning in general that could "help students compensate for missing linguistic skills" (p. 175) included, in terms of reading, the opportunity to receive organized instructor feedback in writing. Some students also used online resources that they looked up in their first language to help them understand some of the concepts they were studying. Another benefit reported by international students in the same study and elsewhere (e.g., Park, 2006) was having course content and online discussions available to review at one's leisure. Asynchronous learning provided opportunities for self-directed learning for some of the students in Rodríguez Manzanares' study, as they took advantage of the opportunity to have "any-time access to online resources by means of independent online searching, outside of the learning management system" (p. 186). In fact, engaging in self-directed learning might be important for international students in online courses, as highlighted in Park's study. All of the study's participants were Asian and some of them had difficulties to "motivat[e] themselves without teachers pushing them to study[, as] they were accustomed to strong direction from teachers" (p. 96).

The studies also identified some disadvantages of online asynchronous learning for international students in online courses. Jusung and Park (2003), Park (2006), and Zhang and Kenny (2010), among others, identified disadvantages that related specifically to online discussions. Jusung and Park, who focused exclusively on online discussions in their study, relied on data from more than 1,000 online postings, whereas Park conducted interviews and Zhang and Kenny relied on an online survey, online observation, and email and telephone interviews. The disadvantages of online discussions for international students were highlighted

in relation to English language proficiency issues. For example, Park commented on students feeling the pressure to write well written, long messages in English. Zhang and Kenny reported on some of their findings as follows: “Non-native speakers of English were not very confident about their English proficiency and spent considerably more time than their English-speaking peers reading and composing messages [and] preferred to read others’ postings first rather than initiate a message....” (p. 28). JuSung and Park also reported on international students not initiating discussion but focusing on replying to others, one of the reasons being difficulty catching up on reading in discussions with numerous postings.

Besides students’ English language proficiency, other “cultural conditions” (Zhang & Kenny, 2010, p. 28) could affect their participation in online courses and, more specifically, in asynchronous discussions. Students in Zhang and Kenny’s study who had less experience in North American learning settings “tended to think that other course members were more knowledgeable” (p. 28), which diminished their confidence in their ability to express themselves in English. Some students were concerned about delay in communication, as they anxiously waited for replies “assum[ing] that if their posting did not get a response, it might mean they did not express themselves clearly or that their message was interpreted as offensive” (p. 28). As with some Asian students who may not consider it appropriate to challenge the ideas of others, some students in their study were “reluctant to argue with peers in a public forum if they did not agree with somebody’s opinion” (p. 27). Sheu (2005) also reported on most international students in her study, who were from an Asian cultural background, being “uncomfortable... communicating in a public environment such as a discussion board or chat room” (p. 93). Park (2006) and Jusung and Park (2003) found that international students received fewer responses from domestic students. Jusung and Park in addition reported on responses showing “excessive sympathy” (p. 9). The international students in

their study also relied on more frequent use of “powerless language” (p. 7), as illustrated in their use of question tags, hedges, and disclaimers.

Synchronous Online Learning: Advantages and Disadvantages

Students in some of the studies (e.g., Park, 2006; Rodríguez Manzanares, 2012) believed that they could have benefitted from synchronous sessions, had they been available in their online courses. In Park’s study, participants suggested including office hours (whether face-to-face or synchronously online) instead of using email, which meant having to wait for a reply. Although synchronous voice- or text-based sessions might “provide the immediacy that would otherwise be lacking with asynchronous interaction” (Rodríguez Manzanares, 2012, p. 182), they can also present disadvantages related to access to the sessions because of students’ time zones as well as responsibilities such as work-related ones (e.g., Liu et al., 2010; Zhang & Kenny, 2010).

Wang and Reeves’ (2007) study, which relied on interviews and observations to investigate international students in an online synchronous course, identified additional challenges related to these students’ participation in synchronous sessions. Students “could not listen to the lecture and read... instant messages at the same time[, as they] struggled to deal with multiple information channels....” (p. 353); however, it was not possible to ascertain to what extent this challenge might have been caused by language barriers. The students were also nervous “because they had to speak about their ideas online, because they were afraid of making language mistakes, and because of their fears that other classmates might not understand them” (pp. 347-348). Native English speakers spoke too fast for them to be able to follow during the synchronous sessions. Other findings of the study related to students feeling that, compared to face-to-face classes, it was difficult to socialize and establish friendships in online courses because of lack of non-verbal cues.

Participants in Wang and Reeves' (2007) study reported on developing friendships among each other when working in a group project. However, all of them believed that students in an online synchronous course would still need some face-to-face interaction. The lack of visual cues, according to the students, made it harder for them to capture their classmates' ideas, whereas being able to see others would have helped "understand different accents and guess what they were saying" (p. 348). On the other hand, the study's observations suggested that "none of [the participants] adopted strategies to minimize distractions during class" (p. 347), as they engaged simultaneously in activities such as web surfing and attending to personal phone calls, emails, or text messages.

Contrasting Findings

There were contrasting findings in some cases among individuals in the same study, as different students had different perceptions regarding online courses. For example, the findings of Tan et al.'s (2010) research in relation to lack of visual cues in online courses illustrate this point: "While some participants saw the lack of face-to-face contact... as a liability, others perceived it to be a benefit, [as] they were able to keep pace with communication better and comprehend more... than they would have in... face-to-face courses" (p. 13).

In some cases, there were contrasting findings among studies. For example, unfamiliar references, as Zhang and Kenny (2010) noted, could affect the participation levels of international students in online courses. In their study, "students with strong English language proficiencies and Western cultural backgrounds tended to dominate the discussion forums" (p. 29). In contrast, Park's (2006) study highlighted that international students, because of the delay associated with asynchronous interaction, could look for context when encountering unfamiliar references in their courses. Text-based interaction was for that reason "less threatening" (p. 101) for them.

The graduate international students in Tan et al.'s (2010) research were dissatisfied in relation to issues related to cultural inclusivity in their online courses, "holding the perception that very few instructors and peers pay attention to such issues" (p. 12). However, in Liu et al.'s (2010) study, which was also conducted with graduate international students, participants "noted different culture patterns in online collaboration and communication but indicated that these differences did not affect their learning in a negative way" (p. 183). These different patterns related, for example, to a collectivistic orientation, which is what the international students were accustomed to, vs. an individualistic orientation. The participants' perception regarding different cultural patterns may have related to the fact that they were Master of Business Administration (MBA) students who worked in large global companies. Their experiences working with international customers may have made them skilled in dealing with cultural difference, which, in relation to what they encountered when learning online related to, for example: different assessment styles in the United States and in their countries (process-oriented vs. examination-oriented styles and a focus on application vs. memorization); different rules of conduct, such as those regarding citation of others' work in written assignments; and differences in instruction and interaction related to a focus on conversing vs. lecturing, on induction (through reliance on cases in the MBA courses) vs. deduction, and on less structured vs. more structured instruction.

There were differences among some studies in relation to the importance that international students ascribed to socializing in online courses. Rodríguez Manzanares (2012) and Sadykova (2014) found that some international students may want to establish friendships with domestic students and participate in cultural exchange. Sadykova's mixed methods study, which included survey and interview data as well as data from a case study of one student, found that establishing personal friendships with domestic students might

be a matter of necessity for international students in online courses. She also found that, in online courses, these students may benefit from close ties with domestic students in order to help them learn about academic cultural conventions in the host institution and to “satisfy [their] interest in the host culture” (p. 43). The case study in particular “demonstrated the significance of social relationships that students, especially those who come from collectivistic high-context cultures, may seek in any format of learning – online or traditional” (p. 43). However, in Zhang and Kenny’s (2010) study of graduate international students, participants did not consider social interaction necessary. Some of them thought a space for socializing in online courses was “somewhat important,” but they “did not perceive it as critical for their learning” (p. 28).

Recommendations for Practice Identified in the Studies

The studies of international students in online courses identified recommendations for practice that referred not only to teaching but also to course design as well as support services. In some cases, recommendations were suggested by participants themselves (e.g., Park, 2006; Rodríguez Manzanares, 2012). Rodríguez Manzanares (2012) discussed in her study some of the recommendations for practice that have been identified in her research and other research on international students in online courses, which included adding some face-to-face interaction, whenever possible, and adding online synchronous interaction (e.g., for office hours) as well as asynchronous video or voice recordings, if these are not already part of the learning environment. Additional recommendations related to enhancing language-related services and supports, such as, for example, by offering support with writing skills for off-campus international students registered in online courses. In addition, instructors could support international students and students in general in online courses through provision of timely, extensive

feedback. These types of support could in turn help enhance teaching presence, which might be important for international students who are used to receiving direction from instructors. At the same time, instructors and course designers could focus on designing courses and providing course-related supports that facilitate more self-directed, independent student learning. In this regard, they could provide carefully designed opportunities for peer support and collaboration. In terms of issues related to cultural inclusivity in online courses, designers and instructors could focus on including global topics and cases in online courses, having some choice for students regarding topics for assignments, and providing information regarding cultural references which might be unfamiliar for international students. Finally, international students who want to establish friendships or participate in cultural exchange in general might benefit from the provision of opportunities in online courses for students to seek social interaction.

FUTURE RESEARCH DIRECTIONS

Studies of postsecondary international students learning in online courses have tended to include students as participants. Future studies may include also other individuals, such as online course designers and other learning specialists as well as course instructors and administrative and support personnel. In addition, most of the studies fitted within a qualitative research paradigm, except for Liu’s (2008) and Sheu’s (2005) studies, which fitted within a quantitative research paradigm, and Sadykova’s (2014), which relied on mixed methods. With the numbers of international students increasing at the postsecondary level and online course offerings also increasing, there might be growing interest among researchers in conducting further research on international students in online courses, which may result in more studies being conducted which fit within quantitative or mixed methods paradigms.

There were contrasting findings in some cases among individuals participating in the same study, as different students within the same study could have different perceptions regarding online courses (e.g., Tan et al., 2010), as outlined above. As also discussed above, there were contrasting findings among studies, for example in relation to the importance of socializing for international students in online courses (e.g., Sadykova, 2014; Zhang & Kenny, 2010). These types of contrasting findings emphasize the importance of paying attention both to the context of individual participants and of their learning setting in future studies of international students in online courses. Regarding individual students, detailed descriptions might be needed of their personal characteristics, including their cultural backgrounds and previous learning experiences in general as well as in relation to technology. As regards the learning setting, detailed descriptions could be provided of the types of tools used in the students' courses and of what tools or supports students may have relied on outside of their courses to help them learn. In-depth case studies of online courses or programs in which international students participate might help provide further insights into their learning.

CONCLUSION

For several decades, postsecondary institutions have focused on internationalization, particularly those in developed countries (Arabkheradmand et al., 2015). Arabkheradmand et al. have referred to a view of internationalization at this educational level as “a necessity, not a mandatory or even beneficiary but rather an existential requirement for every educational center in the twenty-first century” (p. 1). The two educational trends that were the focus of this article, an increase in numbers of postsecondary international students and an increase in online course offerings (with their potential for global reach), provide an illustration of some of the intersecting facets of international-

ization in postsecondary institutions. As the two trends continue, there might be greater interest among researchers in conducting more studies of postsecondary international students in online courses, which might help alleviate the current paucity of research in the area.

KEY TERMS AND DEFINITIONS

Foreign Students: Used synonymously with the term international students in some contexts, whereas, in other contexts, foreign students are considered to be a subset of international students.

Higher Education: See Postsecondary Education.

International Students: As traditionally defined, international students are those who cross borders in order to further their education.

Online Course: A course delivered using online technologies and, for the purpose of this article, a course delivered fully online, without face-to-face components being part of its design.

Online Asynchronous Learning: Learning delivered using technologies allowing for asynchronous (not in real time) interaction.

Online Synchronous Learning: Learning delivered using technologies allowing for synchronous (in real time) interaction.

Postsecondary Education: Education beyond the high school (secondary) educational level.

Tertiary Education: See Postsecondary Education.

IT Solutions Supporting the Management of Higher Education Institutions in Poland

Elżbieta Janczyk-Strzała

Wroclaw School of Banking, Poland

INTRODUCTION

Operating as they are on the contemporary difficult and dynamic market, higher education institutions (HEIs) should strive to ensure suitable conditions for a continuous furthering of their educational mission. Demographic changes and competition force the authorities of HEIs to effectively manage their resources and potential. It is vital then that HEIs, through the use of sophisticated information technology, draw from the opportunities offered by multi-dimensional reporting tailored to the requirements of specific customers. The present paper presents various IT solutions that can assist HEIs by supporting effective management, administration and organization of their work. It is a result of literature studies, empirical research and own experience of the author. This publication fills a gap as a source of information about IT solutions and their application in such specific entities as higher education institutions. It shows the great role and importance of information for HEI management purposes.

BACKGROUND

The beginnings of higher education go back to antiquity when the Athenaeum was founded in Rome by Emperor Hadrian as well as the university of Alexandria. However, proper multi-departmental higher education institutions appeared only in medieval Western Europe. Among them were the University of Bologna (approx. 1088), University of Oxford (approx. 1167), University of Paris (approx. 1170), University of Cambridge

(approx. 1209) and University of Padua (1220). (*Selekcyjna funkcja...*). The first Polish university was the Kraków Academy founded in 1364. It was the second oldest university in Central Europe, after Charles University in Prague (1348) (see: www.uj.edu.pl). At the beginning of the Second Polish Republic, after the period of partitions of Poland, there were five universities (in Kraków, Vilnius, Lviv, Warsaw and Poznań), two technical universities (in Lviv and Warsaw), Szkoła Główna Gospodarstwa Wiejskiego (Warsaw University of Life Sciences), Mining Academy in Kraków and the Academy of Veterinary Medicine (Lviv) (Jaczewski, 1987, pp.206-210). WWII brought severe losses to Polish science. By the decision of the occupier, higher education was to be eliminated. In 1945-1989, during the period of People's Poland (PRL), first under Stalin and then under the socialist regime, higher education was under a strong political indoctrination. Management of higher education institutions was partly in the hands of the central administration (Thieme, 2009, p.229). In 1989 the number of HEIs went up to 97 while the number of students reached 378,000. They were only state-owned institutions with only one exception for the Catholic University of Lublin (KUL) which is a non-public university whose founding body is the church.

Since 1990s, higher education has been undergoing numerous transformations. The Higher Education Act enacted by the Polish Sejm on 12 September 1990 provided legal framework for the development of non-public education in Poland. The next law of 26 June 1996 on higher vocational schools regulated the activity of schools offering only vocational education and awarding bachelor

Table 1. Number of students in Poland in 1999-2011

Academic Year	All Students	Students Number Indicator (1990/1991=100)	Academic Year	All students	Students Number Indicator (1990/1991=100)
1990/1991	390409	100	2001/2002	1718747	440
1991/1992	414609	106	2002/2003	1800548	461
1992/1993	481273	123	2003/2004	1858680	476
1993/1994	568702	146	2004/2005	1930917	495
1994/1995	666712	171	2005/2006	1953832	500
1995/1996	779907	200	2006/2007	1941445	497
1996/1997	917939	235	2007/2008	1937404	496
1997/1998	1082657	277	2008/2009	1927762	494
1998/1999	1265347	324	2009/2010	1900014	487
1999/2000	1421277	364	2010/2011	1841251	472
2000/2001	1584804	406	2011/2012	1764060	452

Source: *Szkoły wyższe i ich finanse 1999-2011 [HEIs and their finances 1999-2011]*, Warsaw.

or engineer degrees. The Law on Higher Education systematised tertiary education and introduced a division into first- and second-cycle studies. Additionally, some institutions offer individual programmes of studies or regular studies in a foreign language.

From the academic year 1990/1991 the number of students was growing until the year 2005/2006 when it reached its peak at 1.95 million. Since that time, the number of students has been on a gradual

decline. The above changes can be attributed to the decreasing population aged 19-24, to Poland's EU accession which offered Polish prospective students the opportunity to study abroad, and are also probably a consequence of amendments to the Law on Higher Education that introduced tuition fees for pursuing a second and other degrees (Report "Higher Education...", 2013).

As forecasted by the Ministry of Science and Higher Education, in the following years the above

Figure 1. Number of public and non-public HEIs in Poland

Source: *Szkoły wyższe i ich finanse w 2012 [HEIs and their finances in 2012]*, Warsaw, 2013, p.31

number will continue to fall until 2025-2026 when it will reach 1.26 million. In the next years it is expected to grow steadily until 2030-2035 when it will reach a level recorded at the turn of the 21st century.

FEATURES OF IT TOOLS SUPPORTING HEI MANAGEMENT

Operating as they are on the contemporary difficult and dynamic market, higher education institutions should strive to provide suitable conditions for the fulfilment of their educational mission. Various IT tools may turn out to be helpful, supporting the process of managing the higher education institution, by facilitating the gathering, processing and transfer of information. Therefore, the process of building a given IT tool is of paramount importance. It should have the following features (Vollmuth, 2000, pp.84-85; Janczyk-Strzała, 2008, p.41; Janczyk-Strzała, 2013, pp.166-167):

- **Currency:** Present information relevant for the reality at hand.
- **Economy:** Present only the necessary data.
- **Objectivity:** Making sure that no “window dressing” takes place.
- **Consistency and Stability:** Ensuring data comparability thanks to predefined and fixed reporting system.
- **Clarity:** Use of unequivocal terms and phrases (without undue “theoretising”), numerical data and discussions supported by suitable graphics.
- **Single Source of Information:** Ensuring data consistency.
- **Recipient Focus:** Adjusting of the scope and degree of detail of the data to the information needs of individual recipients.

The choice of a suitable IT tool supporting planning, control and coordination determines the effectiveness of the entire HEI management process. For the above reasons, the manner of

presenting information for various levels of HEI management should be different (Figure 2).

TYPES OF IT TOOLS SUPPORTING HEI MANAGEMENT

An information system must be adjusted to the situation of a HEI, to its needs and capabilities. Its purpose is to ensure proper evaluation of the HEI's position (through an analysis of the processes taking part in it) as well as of the process of implementation of its strategy (in the context of opportunities and threats). For the above reasons, HEIs should use the following *IT tools supporting their operation*:

- Universal office software packages (mainly spreadsheets, word processors and database management software),
- Dedicated software,
- Integrated HEI management systems,
- Company websites based on website building technology.

The features of above IT tools are presented in Table 2.

Users of the above tools must remember that the IT systems supporting HEI management must meet the requirements of the law (among others general statutory requirements, regulations applicable to higher education institutions or EU legislation in force in Poland). They should also be adapted to the needs, operating conditions and capabilities of the HEI in question.

EXAMPLES OF IT SOLUTIONS FOR HIGHER EDUCATION INSTITUTIONS

For the purposes of this paper, an analysis has been made of the various IT tools supporting the operation of educational establishments in Poland. The research was conducted in February-April 2015. The research results show the possibilities

Figure 2. Management level and type of information presented

Source: Own data.

offered by the analysed solutions used to enhance internal procedures and to support various business processes and the performance of statutory duties. The IT technology presented below is used in the management of individual educational institutions (HEIs), but some of them also serve to provide information for the management of the national education system as a whole.

HEI Management Systems

The research showed that a half of Polish HEIs use in-house developed computer programmes. They serve individual areas of the institution's activity (e.g. bursary, teaching, research, etc.) and require coordination and integration through the use of suitable interfaces enabling the flow of information between them. Some HEIs still use manual transfer of data between systems.

If a HEI does not want or cannot develop a dedicated software in-house it may use solutions available on the market, such as:

- Bazus (admissions, student registry, virtual dean's office, class planning, student ID or dormitory management),
- HMS Solutions (supports the work of the dean's office, bursary, HR and payroll),
- Sokrates (admissions, records and accounting of credits/examinations, reporting and statistics),
- Uczelnia.XP (supports the admission process, teaching, accounting of teaching hours and management of dormitories),
- USOS (supports the management of courses of study).

Table 2. Features of IT tools supporting HEI management

Type	Properties	Advantages	Disadvantages
Office package	• universal • easily available and popular	• the most cost effective solution available on the market • easy to use (does not require any professional IT training), • small financial outlays (costs of licence and implementation of the software), • precisely and quickly adjustable to the current information needs of the HEI • highly flexible	• limited possibilities of processing a large number of data • limited capabilities for multidimensional analysis
Dedicated software	adjustable to the needs and requirements of the HEI	highly adjustable to the specific features of the sector, environment and size of the institution	• requires considerable financial and time outlays • risk of dependence on a single contractor
Integrated Management System	• modular architecture • flexibility - range of functionalities may be adjusted through using basic and additional functions • open architecture - individual modules are self-sufficient but may also be connected to external databases • modularity - possibility to introduce new applications individually (e.g. starting with Accounting and then adding Reporting), • central database - shared by all the modules and enabling the flow of information between them • adjustable to the specific user requirements (through suitable parameter settings) • technologically advanced	• enables cost control – through full control over information and HEI activities by using various system functionalities • increased productivity - easy to use and intuitive user interface enabling efficient work • controllable, systematized and continuous data recording • offers immediate data analysis for any time period • global reach – e.g. multi-currency (the transactions performed can be recorded in multiple currencies) • revenue increase – immediate access to information from various parts of the system leads to quick responding of the HEI to the emerging opportunities and threats, better customer service and to improved cooperation with other parties	• high implementation costs • dedicated mainly for large and medium-sized institutions • benefits grow only after several modules have been implemented
Company website	modularity and independent operation of individual components	• scalability • quickly extendable functionalities • adaptable to user needs (website layout and functions can be configured) • dynamic content management (easy and quick content updating) • security (state-of-the-art data security features)	very expensive (price exceeds even IMS)

Source: own study based on: Janczyk-Strzała, 2008, pp.43-44.

Dedicated software is adjusted to the specific features of the education sector and to the needs and requirements of individual HEIs. To learn more about dedicated systems, see: *Raport końcowy "Modele zarządzania uczelniami w Polsce"* [Final Report "HEI Management Models in Poland"], 2011, pp. 240-241.

Some larger institutions offering MA programmes have implemented integrated systems. They are advanced tools supporting the process of non-public HEI management. Their implementation is not an easy task, as it requires the involvement of many people from various areas of the institution, as well as significant financial

outlays (e.g. for licence purchases, for the implementation, employee training and purchase of the necessary IT equipment). Additionally, their implementation requires organisational changes within the HEI involving for instance organisational structure, work organisation in individual departments or the flow of information between them. Although the implementation of the above systems is not a fast process, once successfully completed, it may contribute to optimising internal processes as well as the processes taking part in the close environment of the institution. The systems in question are comprehensive, have flexible structure and functionalities, and offer technologically advanced solutions supporting the management of various areas of the HEI. Their architecture is usually modular, with each module responsible for supporting a different function of the institution (e.g. accounting, controlling, HR, project or investment management). On the Polish education market, systems of the above class have been mainly implemented at public HEIs (e.g. Impuls 5, Microsoft Dynamics, SAP, SIMPLE.ERP, Teta Constellation), but recent years also witnessed a couple of examples of ERP system implementations at non-public schools – such as for example SAP or SIMPLE.ERP.

E-Learning Platforms/Systems

When offering e-learning under the distance-learning system, HEIs may use a number of various tools, starting from email, through a website enabling access to digital study materials, to integrated IT systems which are becoming more and more popular (also referred to as e-learning platforms) supporting the study process at its individual stages. The above systems comprise:

- **Authoring Systems (AT):** Original tools used for the preparation of e-learning courses.
- **Learning Management Systems (LMS):** Referred to as LMS platform or e-learning platform; a system enabling course ad-

ministration and content presentation. The system enables course launch, registration of participants and participant progress tracking.

- **Assessment Systems (AS):** Assessment systems used for designing, drafting and servicing of electronic tests/examinations.
- **Learning Content Management System (LCMS):** Apart from the functions of an LMS, it has modules used for creating teaching content (Caniëls, Smeets-Verstraeten, Bosch, 2007).
- **Course Management Systems (CMS):** Systems used in the management of training processes offering automation of management, administration and reporting of e-learning results.
- **Virtual Learning Environments (VLE):** Platform enabling uploading of teaching content in the form of courses for a closed user group with a possibility to extend the system to include new accounts and user groups. It is composed mainly of the curriculum, timetable and teaching materials (e.g. animations, video).
- In Poland, the dominant educational platform is Moodle whose popularity is chiefly owed to the free GNU General Public Licence that enables to avoid the additional costs of purchasing the system (Zieliński, 2007). There are also other systems such as ILIAS which, like Moodle, is based on the GNU GPL licence.

The following are possible applications of learning platforms:

- Ready-made commercial learning platforms used for the design of training sessions (e.g. IBM's Lotus LearningSpace platform – used by the Warsaw University of Technology).
- **Original Solutions Designed and Created by Individual HEIs:** They can incorporate individual elements of ready-

made systems or such elements may be built from scratch (e.g. e-sgh platform at SGH - Warsaw School of Economics, EDUX at the Polish-Japanese Academy of Information Technology).

- **Rented Learning Platforms:** Used for specific training sessions when the institution does not wish to purchase the entire platform. Such rentals are offered for instance by Alatus or Oracle (for more on the subject, see: Nojszewski D., Platformy...).

First attempts can be observed at pooling the efforts of several institutions to exchange experience and at building a common learning platform. Among the examples is the Warsaw University of Technology with its Wirtualna Politechnika project (<http://www.okno.pw.edu.pl/>).

Electronic Documents Flow

To optimise the costs of clerical services (streamline the flow of incoming and outgoing mail) and to reduce the time of documents flow, an increasing number of large HEIs decide to introduce electronic documents flow. The above relates primarily to multi-department HEIs, which use the above method to minimise the risk of loss of documents, including in particular financial documents. Thus, among the immediate results of the implementation is increased security of the institution and a significant improvement in the efficiency of its internal processes. Electronic documents flow is a scalable system, so it can be tailored to the specific features and needs of any HEI. Additionally, a document flow system may be integrated with other systems implemented at the HEI, such as ERP, proprietary systems, website, etc.

Polish HEIs may choose from among a dozen or so products. Among the examples of systems used by higher education institutions are:

- **DocuSafe®:** Used by the Wrocław Medical University, Strzemiński Academy of Fine

Arts Łódź and Cardinal Stefan Wyszyński University in Warsaw, Maritime University of Szczecin, Casimir the Great University in Bydgoszcz or Poznań University of Medical Sciences

- **SIMPLE.EOD (by SIMPLE):** Used, among others, by the University of Łódź and the Częstochowa University of Technology
- **CONTMAN DIRECTOR (by Opt Team):** Implemented at the Kazimierz Pułaski University of Technology and Humanities in Radom
- **OfficeObjects@Document Manager (by Rodan Systems):** Warsaw University of Technology
- **Dokumenty (by BETASOFT)**
- **EOD (by PARTNERS In PROGRESS)**
- **OPTiRCM (by OPTeam S.A.)**
- **Comarch Workflow (by Comarch)**

It should be stressed that the significance attached to electronic flow of documents has reached a level that made it a subject of the 6th Forum of IT University Management held on 25 March 2015 which included presentations on electronic documents flow, automation of business processes or document archiving (for more on the forum see: <http://docusafe.pl/author/admin/>).

Plagiarism Detection Software

In order to ensure originality of diploma theses, HEIs have implemented verification mechanisms including supervisor guidance during the seminar, student's declarations of originality of their diploma projects, thesis reviews and diploma examinations. Moreover, since last year, HEIs have had a statutory duty to implement plagiarism detection measures using specialist software. The above software detects similarities between the student's work and earlier papers published on the Internet or stored in the systems.

Plagiat.pl is the leading plagiarism detection software on the Polish education market. Ac-

cess to the software was purchased by 185 out of 441 public and private HEIs (according to 2014 data <http://prawo.rp.pl/artykul/1080058.html?print=tak&p=0>, retrieved on 23 April 2015). The software enables to generate a similarities report providing the following information:

- “The so-called similarity index, showing what percentage of the verified text is identical with texts in the database or on the Internet.
- List of the longest fragments identified by the system as identical with those in the database or on the Internet.
- List of sources in which fragments of texts are identical with fragments of the submitted text.
- Text of the submitted document with marked fragments identified as identical with fragments of texts from the database and from the Internet.
- All fragments allegedly copied from a specific document marked with a specific colour – which facilitates the assessment of their type” (according to data given on the website informing about the system https://www.plagiat.pl/webplagiat/main.action?menu=important_info#subject, retrieved on 23 April 2015).

Each HEI sets its own rules for interpreting the report as well as for other areas of system operation. Usually the above report is generated by dean’s office employees, and where a high percentage of copied text is detected its results are transferred to the thesis supervisor and/or to a special committee.

Apart from Plagiat.pl, there are other systems available on the Polish market, of which the following should be mentioned:

- **OSA Open Plagiarism Detection**
System: Developed by the Interuniversity Computerization Centre (MUCI), composed

of universities from, among others, Warsaw, Wrocław, Kraków, Katowice, Poznań and Lublin, in collaboration with the Institute of Fundamentals of Informatics of the Polish Academy of Sciences. Unlike other systems, this one does not use directly the papers in their original form but it uses data structures storing fragmentary information about the texts – the so-called incidence vectors and maps (<http://osaweb.pl/index.php>, retrieved on 23 April 2015).

- **SowiDocs:** Developed by the Gdańsk University of Technology. It enables searching similar documents, searches identical fragments (copy-paste) and similar fragments (copy-edit-paste). It is a part of the comprehensive system of intellectual property protection (SOWI) and may be extended to include a system for diploma thesis archiving – Digital Document Repository (RDC), a platform for the student-teacher cooperation and a platform offering access to diploma theses (<https://sowi.pg.gda.pl/index.php/pl/content/ap-usage>, retrieved on 23 April 2015).

The OSA and SOWI systems were presented during the European Anti Plagiarism Forum EFA 2014, the first Polish conference devoted to plagiarism detection solutions for HEIs hosted by the European Forum of Law and Education on 24 October 2014. Conference participants also learned about two other systems used in other countries – Turnitin (popular in the UK) and about the Sweden’s Urkund.

It should also be stressed that there are free programmes available on the Internet for detecting plagiarism of intranet content; they can be used by students at the stage of verifying their Bachelor’s/ Master’s theses (e.g. Antyplagiat.net.pl). Reviewers who often check papers on similar topics, also have a possibility of verifying whether a given piece of text is repeated in other files saved on their computer (e.g. using AntiPlagiarist).

Other Examples of Modern IT Technology Dedicated for HEIs

Other examples of modern IT solutions that more and more frequently support the operation of contemporary higher education institutions include:

- **Digital Libraries:** Offering online access to digital publications as well as to digitised hard copy publications,
- **Digital/Virtual Dean's Office:** Among other places, the functionality is implemented at the Pontifical University of John Paul II in Kraków, University of Economics in Katowice, Lodz University of Technology, Warsaw School of Economics, Cracow University of Economics, School of Administration in Bielsko-Biała or the University of Dąbrowa Górnicza. It enables the use of network resources supporting the school's teaching process,
- **Electronic Student ID Card:** Introduced in the regulation of the Minister of Science and Higher Education of 2 November 2006 on course of study documentation (Dz. U. of 2006 No. 224, item 1634). It is in the form of a chip card. The card enables personalization of the ID, as it may be associated with a banking card or with an electronic key (access to laboratories), etc. It may also be used as a public transport pass (under the URBANCARD system).
- **Electronic ID of HEI Employee:** May be issued to administration employees, teachers and academics. It offers a number of functions, depending on the holder's rights – such as for example user identification, logging into workstations, work time tracking, access to buildings/premises/parking lots or to library resources,
- **Electronic Admissions:** Enabling online registration by filling out a special admissions form,
- **Information Kiosks:** Multimedia computers available to students 24/7 (also beyond

working hours of dean's offices or other administrative departments) placed at various locations on university premises; offered mainly by private HEIs,

- IT tools supporting staff management and offering, among others, employee assessments or evaluation of research output.

INFORMATIZATION OF HIGHER EDUCATION INSTITUTIONS IN THE CONTEXT OF REPORTING FOR THE MINISTRY OF SCIENCE AND HIGHER EDUCATION

The Ministry of Science and Higher Education has created a higher education information system called POL-on. It is an integrated system composed of a number of modules. The following are among the most important subject areas of the POL-on system:

- **Basic Details of Academic Units and Higher Education Institutions:** The register shows the structure of the higher education and science system. The data collected are publically available and are gathered for information purposes. The register has a functionality that enables access to information about quality assurance system in place at a chosen HEI or organisational unit.
- **Register of Rights Granted to Organisational Units of Higher Education Institutions and to Research Centres to Award Academic Degrees:** The register offers information about units having rights to award the degree of doctor and doctor habilitated in individual areas and disciplines of arts and science.
- **Statement of Rights to Offer Programmes of Study by Field of Study, Level or educational Profile:** It is an informational list presenting all the rights to offer programmes of study in a specified field, of

- a specified level and educational profile that have been granted to HE providers.
- **Nationwide Register of Students:** It includes the most important information about students enrolled in individual courses (both full-time and part-time), including: personal details, number of ECTS points and information about using any financial aid programmes. The purpose of the register is to monitor the financial aid offered and to manage tuition fees.
 - **Register of Research Employees and Academic Teachers:** The register is kept to verify if a given HE unit meets the requirements for minimum academic staff complement at individual departments, as well as to keep track of other jobs held by employees as well as to verify the HEI's rights to award academic titles and degrees.
 - **HEI Reporting:** The purpose of gathering the data is to streamline the reporting process and to remove the burden from the institution by replacing the financial statements filed with the Central Statistical Office (GUS), MNiSW (Ministry of Science and Higher Education) and to the Ministry of Finance with a single standard report.
 - **List of Science Promotion Events:** The purpose of the list is to gather data about awards and distinctions granted to individual institutions or their employees. The list also includes information about scientific conferences hosted or co-hosted by a given unit.
 - **Registers of Real Estate, Infrastructure, Laboratories and Apparatus:** A generally available database gathering information about research resources of research units open to a broad group of prospective users, both from the academic and industry sector.
 - **List of Patents and Achievements:** Includes information about patents registered, invention applications, rights of protection and copyrights, as well as about implemented products or research results.
 - **Higher Education Unit Survey:** A report that must be filed by all units applying for subsidies from the central government for their statutory activity. On the basis of the survey, a parametric evaluation of the current activity of the unit is calculated and a resulting research unit category is assigned.
 - **CKdsST Electoral System:** The system was used for the conducting of Poland's first fully electronic elections to the Central Commission for Academic Titles and Degrees (<http://polon.nauka.gov.pl/system>, retrieved on 24 April 2015).
- HEIs (as well as research centres) have been reporting to POL-on since autumn 2011 and the scope of this reporting is going to be extended in the coming years. The following modules are planned: statistical module for the Central Statistical Office (GUS), repository of Bachelor's/ Master's theses and doctoral dissertations and a register of diplomas issued by individual institutions.

FUTURE RESEARCH DIRECTIONS

The study discusses the importance of IT tools for HEIs and shows, based on research results, an examples of various IT tools supporting the operation of educational establishments in Poland. Further future improvements of the IT solutions impact of the polish HEIs shall be expected and they may have a positive effect on the Polish education market. Further statistical analysis of the related issues will be one of our future works.

CONCLUSION

These days, given volatile market conditions, competition and the coming population decline, higher education institutions should not only strive to increase the quality of their services and ensure rational management of their resources, but they should be equally focused on investing in state-of-the-art IT solutions and technology that may support and optimize their management. Through the use of suitable solutions and IT tools a HEI can support its management and adjust itself better to internal and external conditions. It can also keep and even improve its competitive position on the education services market.

KEY TERMS AND DEFINITIONS

E-Learning Platforms: Platforms/systems used in teaching with the use of the Internet and of computer networks.

Electronic Documents Flow: IT system used for managing the flow of work and documents.

Gross Enrolment Ratio: Ratio between the number of students enrolled in tertiary education and the entire population of the age nominally assigned to tertiary education, expressed as a percentage.

Informatization: Process aimed at improving information systems, control systems and other systems through the use of computer equipment.

Integrated IT System: IT system supporting management, with modular or integral architecture.

Knowledge Networks in Higher Education

Filipa M. Ribeiro

University of Porto, Portugal

INTRODUCTION

The theme of knowledge creation is approached by focusing on the link between creation of knowledge and the relations among actors. This article aims at conceptualizing and discussing knowledge networks in the field of higher education.

BACKGROUND

The role of social networks for the creation of knowledge has been studied outside the educational field, highlighting the crucial role of formal and informal networks in organizational learning by stimulating new knowledge and new practices (Ahuja, 2000; McGrath and Krackhardt, 2003). However, less is known about the role of social networks in the field of education. In fact, up to this point there is only one book published on social networks and education (Daly, 2010).

A social network is a collection of individuals (commonly called actors) and an enumeration of the relations (or ties) among such individuals (Kindermann, 2008). The term social network is depicted from Barnes' work (1954), when he used it to designate the social relationships found in a community in Bremmes, Norway. Since then, the term has been associated to many different types of relations among many different types of individuals. Contemporary networks, unlike local communities, are not only centered on place-based affiliation, but more based on niche cultural affiliations and knowledge communities. These new ways of sharing culture and knowledge have broad implications on the relations between production and consumption and the traditional sources of authority for culture and knowledge. Standards

are continuously being reshaped as networks have become the dominant cultural logic (Varnelis, 2008). "Today, network culture succeeds postmodernism. It does so in a more subtle way. No new 'ism' has emerged: that would lay claim to the familiar territory of manifestos, symposia, definite museum exhibits, and so on" (Varnelis, 2008, p. 149). As it happens in other spheres, universities are made of networked actors¹ and, thus, the cultures that emerge are varied.

In this networked society, the creation and production of knowledge and expertise rises the likelihood that current knowledge will be retained and multiplied in new knowledge and practices. Recent educational studies stressed the importance of strong social networks among teachers for the spread and depth of policy, reform, innovation and change implementation (Coburn and Russel, 2008; Moolenaar, Daly and Slegers, forthcoming; Penuel, Frank and Krause, 2007, Brown and Duguid, 2000; Chiffoleau, 2005; Carre et al., 1989).

Forman and Markus (2005), Drejer and Jorgensen (Drejer & Jorgensen, 2005), and Hkopic et al. (2002), have studied knowledge creation and the role of collaboration. They identified the need for further research on social network characteristics relating to the creation of knowledge in a collaborative research environment. Also Drejer and Jorgensen (2005), and Hkopic et al. (2002), have observed the need for further research integrating the domains of social networking and knowledge creation. These researchers recognized that although collaboration and interdisciplinary research are often recommended, there is still a lack of empirical or theoretical research that validates the role of network sociology in the context of knowledge creation. Forman and Markus (2005) also recognize the value of an area of further

DOI: 10.4018/978-1-5225-2255-3.ch340

empirical quantitative exploration of their own existing qualitative research on this subject.

Moolenaar and Sleegers (2010) tried to find out more exactly to what extent the characteristics of teacher's social networks affect schools' innovative climate, when this is mediated by trust. The authors used a whole network approach, i.e., they focused on specific network characteristics, such as density, reciprocity and centralization, of the social network of the school team as a whole. Findings suggested that the density of the network related to work discussions was significantly associated with school's innovative climate and trust.

Diane Crane (1972) developed a seminal work in trying to understand where the knowledge learnt at universities come from. Who is responsible? Who should wield it? The author argues that the problem of the relationship between the internal structure of a particular cultural institution and the cultural products developed and accepted within has been neglected by the sociology of knowledge. The tendency to view social groups as abstract entities rather than as collections of individuals whose modes of interaction can be precisely observed was probably responsible for this gap. This task requires, as Diana Crane already pointed out back in 1972 (Crane, 1972), the analysis of the development of belief systems of these groups as well as sociometric analysis of the relationships between their members, of the relations between such groups and of the relations of such groups to the larger social structure. The development of social network analysis has been giving a relevant contribution to fill the gap identified by Crane.

In fact, the subsequent development of network theory represented an important contribution to deal with the issue of knowledge as it combined what is intuitively known with a growing body of network research suggesting that relationships within a system matter in enacting change, flows, diffusion strategies, implying both formal and informal networks of social relations that create nets of understandings, influence, and knowledge prior to, during and after any implementation of a change strategy (Daly, 2010).

Gamble and Blackwell (2001) defined knowledge as "a fluid mix of framed experience, values, contextual information, expert insight, and grounded intuition that provides an environment and framework for evaluating and incorporating new experiences and information. It originates and is applied in the mind of the knowers. In organizations it often becomes embedded not only in documents or repositories, but also in organizational routines, practices and norms". Embeddedness in social networks has been considered as a major cause of scientific achievement and scientists' behaviour (Crona & Parker, 2011; Gilsing, Nooteboom, Vanhaverbeke, Duysters, & Oord, 2008). The literature about academic knowledge focuses particularly on how actors' embeddedness within larger structures of co-authorship networks and collaborations in patents and projects is related to individual knowledge outcomes. Less is known about what properties of these networks affect knowledge creation. Knowledge creation studies have mainly focused on the influence of the networks on the efficacy and efficiency by which individuals transfer and apply knowledge (Botero & Cuartas, 2012; Cross, Parker, Prisak, & Borgatti, 2001; Fritsch & Kauffeld-Monz, 2008), but not on how they create new knowledge. This literature provides mixed evidence about the role of relational properties in knowledge creation and dissemination.

Knowledge creation on the other hand, and particularly social knowledge creation, refers to the knowledge that is increasingly created through interactions among the different members of a specific network (or a series of them). It is not only about input/output but rather about the relationship that the individual has with knowledge itself and how that relation is spread through his/her social relationships. Conceptually, creation is linked with creativity and it is known that creative people think and expresses themselves in a relational way (Quintás, 2003). Knowledge creation typically has the forms of ideas, practices, research papers and inventions (Phelps, Heidl, & Wadhwa, 2012), but also, we add, the capacity to create new

knowledge through thematic interrelations which, most times, are created according to the values and empathy among individuals and between individuals and their ideals. In turn, knowledge networks are usually defined as a set of actors who are repositories of knowledge and who create, transfer and adopt knowledge (Phelps et al., 2012). The social connections among these nodes are seen as channels and/or conduits of information and knowledge (Owen-Smith & Powell, 2004). These two definitions emphasise node and tie properties for knowledge creation but they also evidence a lack of understanding on the content of those networks. That is why, we argue that a definition of knowledge network encompasses both the network properties but also the network epistemics. Thus, *knowledge networks* can be defined as epistemic conduits of knowledge.

Networks function as an appropriate device to explore the processes of creation and adoption of knowledge by academics in higher education institutions (HEIs), and how it can be operationalised with the concept of epistemic authority and the analysis of knowledge networks. The claim that underlies this entry is that emergent processes of knowledge creation – in terms of epistemic states – are highly shaped by the social and knowledge networks in which academics are engaged. The primary focus of this approach to knowledge networks will be on knowledge creation. Thus, instead of focusing on the vehicles of distribution of knowledge and scientific outputs (Goldman, 1999), the emphasis will be on the role of knowledge networks – seen as epistemic conduits. This means social networks are the epistemic place where emergent processes of knowledge creation occur.

The claim that networks are epistemic conduits regarding the emergent processes of creation of knowledge also finds support on DiMaggio when the author points out that “intellectual and creative progress is characterized by strong positive network externalities, causing temporal and spatial concentration of significant movements”

and “institutional change often unleashes rapid network elaboration and an explosion of creativity” (DiMaggio, 2011). Also Burt (Burt, 2004) argues that unique occupancy of brokerage positions (‘structural holes’) triggers a wider exposition to novel ideas. Such boundary-spanners, in turn, generate more ideas. Thus, as well as Bourdieu views fields as sites of strategic competition between actors with different levels of cultural capital and economic resources, networks can be linked to epistemic changes in the knowledge created by academics. There are already several studies that support this claim. DeNooy (2003) argued that networks, which are themselves shaped by author’s social origins, form literary genres that double as author identities, which in turn influence social and aesthetic hierarchies. Also Collin’s (1989, 1998, 2000) asserts about how networks drive intellectual movements and he identifies four aspects of how that occurs: 1) intellectual and creative progress is characterized by strong positive network externalities that enhance those movements; 2) the most distinguished thinkers are densely connected to eminent peers; 3) reputational contagion; 4) movement leaders create new ties to extend their influence outward. Crossley (2009) identified similar themes in his analysis of networks that produced Britain’s punk music scene.

In sum, DiMaggio (2011) has argued that cultural products are produced by networks of collaborating creative professionals and organizations; that group and individual identity emerges from relations among people and many types of culture; and that meaning itself emerges from relations among symbols or other elements of texts, broadly defined. However, as the author said:

Longstanding habits of mind – the reluctance of many students of culture, in the social sciences as well as the humanities, to employ formal methods and the radical structuralism explicit in formative contributions to modern SNA – stood in the way of these developments (DiMaggio, 2011:296).

By claiming that knowledge networks of academics are epistemic conduits of their knowledge creation, the notion of epistemology of networks is central to much cultural and knowledge research. Networks are epistemic conduits by making knowledge interpretable and changeable. Thus, SNA can be used in this research to explore how knowledge emerges from the structure of relations among academics as knowledge creators.

Issues and Controversies

There is mixed evidence about the role of relational properties in knowledge creation and diffusion. The literature has stressed the importance of two related relational properties for the diffusion of knowledge in organizations: similarity and tie strength. With regard to the first, social or ethnic similarity (Baycan-Levent & Nijkam, 2010; Mügge, 2011; Rienties, Beausaert, Grohnert, Niemantsverdriet, & Kommers, 2012; Rienties, Hélot, & Jindal-Snape, 2013), similarity in personality and status, and geographic, institutional and organizational proximity (Whitley, 2008) have all been associated with knowledge outcomes, although the associations are ambiguous. On the one hand, similarity increases the ease of collaboration as it increases trust and reciprocity, but on the other hand, similarity lowers the possibilities of new knowledge creation. Furthermore, it is not known whether network similarity affects the motivation of the researcher to innovate and create new knowledge. The lack of understanding in this realm is due to the overemphasis of the role of the collective knowledge and social co-operation, but also on the lack of empirical studies with a deeper focus on the personal and interpersonal level of knowledge networks.

Second, studies have focused on the role of tie strength in knowledge creation and transfer. There is consistent evidence that strong ties (in terms of affinity, tie duration, and contact frequency) are more efficient for the transfer of knowledge by increasing trust and reciprocity norms, and that

they are more efficient in the transfer of certain types of knowledge, particularly complex, tacit knowledge and private knowledge (see Phelps et al., 2012 for a review). Up until now however, there is little agreement on the relative importance of weak and strong ties for knowledge creation. The discussion dates back to Granovetter (1973), who argued that weak ties are more useful for accessing diverse information, while strong ties are better for accessing influence. This distinction between information and influence may provide a clue to long-standing controversies about the relative efficacy of strong and weak network ties. Ruef (2002 and 2003) suggests that, in many cases, strong ties do not provide significant new information, so it isn't helpful to be embedded in clusters of strong ties. Most likely, it is a mixture of strong and weak ties that is necessary for knowledge creation. McFadyen et al. (2009) empirically demonstrate the effects of egonetwork density and average tie strength but also the interaction between these two factors on knowledge creation. They conclude that while strong ties do not provide diverse knowledge resources per se, they are efficient for capturing and using the diverse knowledge made available through sparse ego networks. Sosa (2007) found that strong ties that channel diverse knowledge also play a contributory role in the generation of creative ideas. A third way has been sustained by some authors who defend a complementary view between Burt's social capital theory (1992) and Coleman's theory (1988). Rost (2011), for instance, argues that weak network architectures (structural holes or a peripheral network positions) leverage the strength of strong ties in the creation of innovation.

In short, there is conflicting evidence about whether and under which circumstances tie strength and similarity affect individual knowledge creation (see Phelps et al., 2012).

In order to further explore under which conditions network ties are associated with knowledge creation and transfer, we argue that more attention should be paid to 1) knowledge creation itself;

for instance most literature on knowledge creation and diffusion is based on coauthorship and collaboration networks, but to what extent are these processes important for the creativity and relational creation of knowledge?; 2) the personal level, i.e., the multiple personal networks in which academics are embedded that shape the ways and reasons why they investigate what they investigate and how they actually create knowledge in a relational way. To conceive this, we combine a quantitative personal network approach with a qualitative approach. Our research on knowledge networks stems from a first premise that personal network research has been overlooked in the investigation into knowledge networks in general and even more in knowledge networks in the sector of higher education. The local network that is relevant for knowledge creation is likely larger than collaboration partners alone, and a personal network approach, based on multiple name generators, allows delineating the relevant network. A second premise claims that a deeper qualitative approach brings out benefits for the understanding of the creation and evolution of social networks in research communities. Although both approaches – structural and qualitative – are not new in this research area, to our knowledge, they have seldomly been combined. Therefore, phenomena like knowledge creation have been focused either by actor's attributes or by relational attributes, but separately. There is, thus, a need to integrate the two approaches, which we propose can be achieved by a mixed methods design that combines a structural and a content approach.

To resume, our research aims at going a step further in disambiguating the causal relationships and the content elucidation of knowledge networks, which implications for a deeper understanding of factors that may lead or not to a wider diversity in higher education institutions. In order to do so, this paper locates itself on the interpersonal level of knowledge creation and analyses the influence of tie strength and nodal similarity on knowledge creation.

CONCLUSION

A growing body of empirical research shows that social relationships and the networks these relationships play an important role in explaining the processes of creation, diffusion, absorption, and use of knowledge. Phelps et al. made an excellent review of that body of research.

First, personal network research has been overlooked in the investigation into knowledge networks in the sector of higher education - our empirical work shows a high correspondence between the personal knowledge networks and a permanent structural aspect of knowledge networks that is based on the role played by values on knowledge creation. It is to this personal networks that the respondents stick to no matter what the conjectural fluctuation (academic position shifts, criteria defined by journals, etc.) in their trajectory is. However, this is more due to the personal values attributed to specific ties than to dyadic similarity in other dimensions. Thus, scientific and personal values tend to be more appreciated as drivers for strongest ties than collaboration or expertise.

Secondly, the combination of a quantitative approach with a qualitative one proved to be suitable in the elucidation of the content and context of relations and of the link between actor's attributes and knowledge creation within a network.

FUTURE RESEARCH DIRECTIONS

Research on knowledge networks is still giving the first steps, thus there are plenty of research hypothesis. Knowledge networks research is concerned with how the nature of actors' social embeddedness influences their creation, transfer, and adoption of knowledge. Social embeddedness is, however, only one form or source of embeddedness (Dacin, Ventresca, & Beal, 1999). Other sources include informal cultural systems of meaning and formalized political-legal institutions (Dacin et al., 1999; Zukin & DiMaggio, 1990).

Regarding the network epistemics, one challenge worth exploring is how to leverage knowledge from other networks or from different networks. Our proposal intends to move a step further in understanding the links between network structure, perceptions, and actions in a dynamic field of interaction such as knowledge creation at universities.

KEY TERMS AND DEFINITIONS

Knowledge Networks: Usually knowledge network is the term given to different types of team or social networks and communities that are recognized to add significant value to the creation, dissemination and application of knowledge. In the scope of our research on processes of knowledge creation is a conceptual and structural device that reflects how individuals deal with problems, situations, and make sense of phenomena; they are the epistemic conduits by which circulates the know-how (and know-why) that individuals call on to accomplish their work.

Knowledge: A fluid mix of framed experience, values, contextual information, expert insight, and grounded intuition that provides an environment and framework for evaluating and incorporating new experiences and information. It originates and is applied in the mind of the knowers. In organizations it often becomes embedded not only in documents or repositories, but also in organizational routines, practices and norms (Gamble and Blackwell, 2001).

Networks Epistemics: Deals with the relationship between social structures of personal knowledge networks and the epistemic choices individuals make regarding the types of knowledge they privilege. Epistemic authority relies upon the

deliverance of experiences provided by the knowledge Networks in which researchers manifest in epistemic states that occur inside network ties.

Social Networks: Channels and/or conduits of information and knowledge. SN research concentrates mainly on 2 types of social networks that reflect different contents or resources flowing through ties. Instrumental social networks are conduits for the circulation of information and resources. These are the most studied. Then there are the expressive networks reflect patterns of more affect-laden relationships. By focusing on epistemics, we also consider meaning, social and personal context, offering the theoretical and methodological lenses through which SNT and sociology tries to answer questions related to the creation and epistemic authority of knowledge, in our case in higher education.

ENDNOTES

- ¹ According to Boyd (2007), there are four properties that separate unmediated publics from networked publics: persistence (they always aim a certain type of prosperity); searchability (identity is established through relations, texts, search and discovery); replicability and invisible audiences.

Quality Online Learning in Higher Education

INTRODUCTION

Traditional education systems alone, despite the essential role they have played and will continue to play in learning, are simply not capable of serving the world's growing and changing needs. The knowledge explosion, driven by the power of the network to connect people and spread ideas, has changed the very nature of learning. We must innovate and develop new modes of learning, both formal and informal, that meet the demands of the knowledge-driven economy in this Information Age. This chapter begins by identifying the technological changes that are affecting all societies and how these changes will specifically impact postsecondary education. The topic of course delivery within this chapter is viewed as a cultural issue that permeates processes from the design of an online course to the evaluation of an online course. This chapter will examine and review key components of, and tools for designing high impact online courses that support student learning and provide suggestions for faculty teaching online courses to assist in creating high quality online courses that supports teaching and, consequently, facilitates opportunities for student learning. Suggestions for conducting course evaluation and a feedback loops for continual improvement of the online learning and teaching will be addressed.

BACKGROUND

Technology broadly defined has been transforming human life in one way or another for thousands of years (Jerald, 2009). However, beginning in the 1990's, this technological change came at an exponentially faster rate due to factors such as increased competition in a global economy, automation, workplace change and policies increasing personal responsibility. As the world's labor markets evolve in the digital economy, we cannot predict what specific jobs will exist in the future, however what is clear is the shift from print to digital is a profound transition in how human beings learn (Pearson Learning, 2014). Currently, there are 84 million students enrolled in higher education worldwide. According to Ryan Craig (2014), "Global demand for higher education is forecasted to reach 160 million by 2025 – if online learning captures even half of this growth, there would be 40 million students requiring online education."

The advent of the personal computer, the Internet and the electronic delivery of information have transformed the world from a manufacturing, physically-based economy to an electronic, knowledge-based economy. Whereas the resources of the physically-based economy are coal, oil and steel, the resources of the new, knowledge-

based economy are brainpower and the ability to acquire, deliver and process information effectively. Ryan Craig (2015) in his new book titled *College Disrupted: The Great Unbundling of College Education*, has argued that “technology may bring more change to teaching and learning than college leaders anticipated.” Online learning will center the learning around students rather than the classroom, tailoring education to the needs and abilities of individual learners, and making life-long learning a practical reality for all (Balanko, 2002).

The global economic crisis and especially the unemployment of youth have prompted the urgency to develop educational systems that are aligned with the needs of the society it serves. Statistics from the United Nations indicate that one half of the global population is currently under the age of 25 years. The Organization of Economic Co-operation and Development (OECD, 2012) has examined this young population from its 33 member nations and concluded that 39 million or one in four 16-29 year olds were neither employed nor enrolled in some type of education or training program.

Those countries that invest in a 21st century education benefit immediately by transforming an outdated system to a more sustainable approach. Educators worldwide must develop challenging and relevant learning environments to prepare the future workforce of tomorrow (Beetham & Sharpe, 2013). Using digital education to connect students anywhere at any time has been touted as a viable option especially where access to post-secondary education is limited (Hosie & Schibeci, 2005). The Internet will “democratize” knowledge, increasing access, lowering the cost and improving the quality. (Moe, 2000). There should be no doubt that online learning is vital to all disciplines involved in education in the 21st century (Ternus, M. et al, 2007).

By 2020, there will be 55 million job openings in the United States. Sixty-five percent will require some postsecondary education. Our current system will fail to produce those skilled workers,

falling short by 5 million postsecondary credentials (Pearson Education, 2014). Ryan Craig (2015), also indicated in his book that the future of post-secondary education online degree programs will focus on “customizing course offerings where there is a true bottom line return for the majority of students in terms of graduation, employment, and wages. “A one-size-fits- all approach, Craig explains, “is no longer viable for the majority of students.” Packaged courses and degrees need to be transformed to smaller units, i.e., modules and micro-degrees allowing students more flexibility in their program of study.

A module is a set of independent units that can be used to construct an online course. An experiment at Massachusetts Institute of Technology is being conducted where students will develop an online course from parts they have assembled themselves online (Craig, 2015). This approach would allow students to retake any module where the student possibly struggled and not require the student to retake the entire course. Another approach is a micro-degree which offers online courses in high demand content areas in the job market. Generally, the online courses, which are an outgrowth of a MOOC, are shorter and allow the student to work at their own pace. A certificate is provided at the completion of the program.

It may first be helpful to highlight three myths and misconceptions about online teaching and learning. These myths/misconceptions are held by students, faculty, and administrators and influence any discussion about the quality of online course delivery (e.g., White, n.d.):

1. Online teaching and learning is ‘worse’ (or ‘better’) for meeting student learning outcomes than face-to-face courses.
2. Online teaching and learning is easier and more convenient for students and faculty than face-to-face courses.
3. Online teaching and learning is less interactive for both student and faculty than face-to-face courses.

All of these statements are based upon the premise that there are no special affordances or constraints of the environment, either online or face-to-face, when it comes to teaching or learning—that we are comparing apples to apples. It has been argued elsewhere that this is not the case, that there are many fundamental differences that the educational environment both affords or constraints (Anderson, 2004; Matuga, 2001, 2005 & 2007) and that establishing a dichotomistic relationship does not adequately reflect the complexity of teaching or learning within either environment. In essence, learning and teaching within online environments is fundamentally *different* than learning and teaching in face-to-face environments. One is not comparing apples to apples, but more like apples to oranges (Matuga, Wooldridge, & Poirier, 2011).

A useful concept to use as a framework, one that more adequately reflects the complexity of online teaching and learning, would be to view both through the lens of a cultural system. There are many definitions of culture and descriptions of what constitute a cultural system. LeVine (1984), for example, defined culture as “a shared organization of ideas that includes the intellectual, moral, and aesthetic standards prevalent in a community and the meanings of communicative actions” (p. 67). Others have claimed that these organizations of ideas and meanings derived from actions are not static and that culture should be thought of as systems that may be more complicated and organic collections of cognitive functions, practices, and meaning (D’Andrade, 2001; Giddens, 1984; Kitayama, 2002). Online teaching and learning may be viewed as cultural systems in that understandings and meanings are socially shared within online environments (Courtney, 2001; Melhinger & Powers, 2002). There are also cultural practices and customs within these environments that may be linked, in various ways, to the values and beliefs of larger cultural systems, like face-to-face educational environments (Courtney, 2001; LeVine, 1984).

A more traditional view of cultural systems, for example, is based upon the idea that they contain within them, nested systems that are interdependent to the functioning of the system as a whole (White, 1975). This view holds that technological (or physical subsystem), social, and psychological factors guide a multitude of functions and influence the behaviors of individuals that are participating in cultural communities (Kityama, 2002; White, 1975). For example, Kitayama (2002) stated that “each person’s psychological processes and structures are organized through the active effort to coordinate his or her behaviors with the pertinent cultural systems of practices and public meanings” (p. 92). While this may be viewed as a valid preposition, this view does imply that there are somewhat distinct sub-systems that guide or organize psychological processes and practices. It may be quite common to reduce discussions regarding online teaching and learning to cultural sub-systems, like technological ones, for example, because the impact of technology may be seen as more explicit within online teaching and learning environments.

This position is arguable in light of contemporary pedagogical theory, however, which would hold that psychological and social factors need to be explored in conjunction with technological ones. Perhaps one of the most critical characteristic of a cultural system is that they support the development and transmission of meaning and understanding within and between participants. Rosaldo (1984) stated that “we must appreciate the ways in which such understandings grow, not from an “inner” essence relatively independent of the social world, but from experience in a world of meanings, images, and social bonds, in which all persons are inevitable involved” (p. 139). In the case of meaning making and understanding within online teaching and learning environments, the importance of viewing the psychological in conjunction with social and technological dimensions of cultural systems is implied. These are important points that frame the conversation of

designing high impact online courses, providing suggestions for faculty teaching online courses, describing critical administrative support of faculty, and conducting course evaluation and feedback loops for continual improvement of online learning and teaching.

Designing High Impact Online Courses

Viewing online teaching and learning as a cultural system provides a framework to describe and understand ‘high impact’ online courses. Within education, ‘high impact’ refers to educational experiences that are meaningful, require student action and participation, and that contribute to the life-long learning of the student (Kuh, 2008). It is important to note that the examples illustrating high impact practices within online courses in this chapter do not represent an exhaustive or comprehensive list, but serve as important points of reference for discussion within this chapter. Two such high impact practices that assist in the design of online courses are pedagogical alignment and meaning making.

Pedagogical Alignment

Pedagogical alignment, also called systematic instructional design (Gagne, Briggs, & Wagner, 1992), entails aligning instructional variables to provide the fundamental framework for online cultural systems, conveying meanings to community participants, and defining cultural activity. Instructional design is currently in the midst of a paradigm shift towards a more situated view of design activity within cultural systems (Anderson, 2004; Derry & Lesgold, 1996; Mayes & de Freitas, 2013). When designing high impact online courses, pedagogical alignment involves the optimum use of a wide array of instructional features including, but not limited to, instructional goals, instructional strategies, and assessment measures and evaluation practices that support teaching and learning (see Matuga, 2005).

The issue of pedagogical alignment in an online course is an important one, for several reasons. While in a face-to-face environment, instructional design and alignment may occur in conjunction with the other during instruction, alignment in an online course, in contrast, is often completed *a priori*. In fact, a clear, comprehensive, and logical course structure may be one of the primary factors which students use to judge whether or not an online course is an effective one. Online course alignment is further complicated by the affordances and constraints stemming from technology and the social and psychological composition of community participants. Each instructional variable is influenced by the affordances and constraints that influence technological, social, and psychological subsystems. For example, discussions regarding effective online course alignment must also incorporate pedagogical and technological expertise of students and teachers in the design process (Chang, Kurcz, El-Bishouty, & Graf, (2015).

There may be several methods in which to assess whether or not pedagogical alignment was effective, more often than not, discussions regarding the effectiveness of online activities are reduced to formal, summative assessment practices such as tests, quizzes, projects, or portfolios. Pedagogical decisions regarding the selection of formal, summative assessments within online courses are important, especially when designing instructional strategies (see Duffy & Cunningham, 2001). However, it is equally important to plan for the manner in which formative assessments and other evaluative information will be utilized to inform other educational practices within the online environment. Teacher and student self-reflection, as a formative, informal assessment to inform learning is a potentially powerful tool for evaluating pedagogical effectiveness.

Another tool to assess pedagogical alignment is peer evaluation of the course itself. There may be many mechanisms and tools that faculty and administration can use that carry out the peer evaluation of online courses. One is a tiered

method at the local level asking more experienced faculty or if available, online instructional designers within the institution to review and constructively evaluate the pedagogical alignment of a particular course. Another method may be to request the course be formally evaluated by peers through organizations such as Quality Matters. Quality Matters is a peer review system of online courses utilizing a rubric that examines pedagogical alignment. While there are costs involved in the later, the former would take some due diligence on the part of the faculty members involved but would one step towards assuring quality in online course design.

Meaning Making

Cultural meaning making is a complex activity tied to the cultural systems in which they are created and shared. One concept that is interesting to explore and is of particular importance to the development of quality online courses is the concept of intersubjectivity. Intersubjectivity is a term associated with Vygotskian theory of cognitive development and refers to the shared cultural understanding between two people (Rogoff, 1990; Rosaldo, 1999; Wertsch, 1985). If there is no shared understanding between two people, for example a teacher and a student, then attempts to communicate, create meaning, and establish understanding are somewhat fruitless endeavors. If the teacher is unable to understand the misconceptions, questions, or understanding of his or her students, then that teacher will not be able to address the student needs and learning will be hampered. It is in this manner that the constraints of an online environment may present challenges to establishment of intersubjectivity (Anderson, 2004). There is the suggestion, that like culture, some meanings may be more explicit due to the “pragmatics of social life and their history for a given society” but not all meanings may be “reduced to its explicit or implicit dimensions” (Le Vine, 1984, p. 77). Social referencing (i.e., gesture, gaze, and other nonverbal communication cues)

which is critical for establishing intersubjectivity (Rogoff, 1990) in a face-to-face environment is not impossible to establish in an online environment, it does, however, take a more concentrated effort in high impact online courses.

The culture of online teaching and learning may share similar characteristics with traditional, face-to-face teaching and learning and there may also be new territory for future investigations. The critical investigation of how teachers and learners understand, navigate, and utilize the culture of online learning environments to become competent participants is critical to the future of designing high impact courses. As Gardner (1984) has stated, “the human being, who, starting from a state of total ignorance about his or her particular culture, must within a decade or two acquire sufficient competence so that he or she can carry out productive work and interact effectively with other individuals to achieve valued ends” (p. 261). The enculturation of teachers and students within online teaching and learning environments requires learning how to use psychological tools within similar, yet dramatically different cultural systems, systems that have different environmental affordances and constraints.

Suggestions for Faculty Teaching Online Courses

There are many resources, books and websites, to assist faculty when teaching high quality online courses (e.g., Cooper, 2015; Eison, 2010; Ko & Rossen, 2001; Koszalka & Ganesan, 2004; Masoumi & Lindström, 2012; Nedungadi, & Raman, 2012). There is also assistance to help faculty effectively utilize discussion boards, online tools, blogs, wikis, open source programs, iPads, iPods, the iGoogle suite, cell phones, etc. within their online courses. Returning to the framework of viewing online courses as cultural systems, two inter-related important considerations are outlined within this chapter for faculty teaching high quality online courses: rituals of participation and co-regulation.

Rituals of Participation

One of the ways in which individuals navigate technological, social, and psychological systems are what Courtney (2001) called “rituals of participation” (p. 236). These rituals for participation encompass the norms and behaviour for participating in cultural activities. Learning how to “do school,” or mastering implicit and explicit academic and social knowledge needed to be successful in school, is an important ritual of participation required for effective teaching and learning (Westby, 1997). This issue is critically important due to the alarming drop rates from online courses by students (Diaz, 2002). Two popular explanations of why online students fail to complete online courses seem to be individual (demographic and/or learning style) or performance (low) differences (Diaz, 2002). However, researchers have suggested that the issue of student preparedness for online classes may be more complicated and include a variety of factors including student, situational, and educational factors (Gibson, 1998).

There may be cross cultural interference between how students conceptualize “doing school” within face-to-face environments and how this concept is challenged and, by necessity, altered within online teaching and learning environments. For example, one affordance within online environments is the ability, on the part of the faculty, to “hear” what every student thinks about a particular subject by requiring all students to post on a discussion board, for example. This, of course, requires that each student contributes to the conversation in a concrete and physical way that reflects what was read, in this there is simply a lot of individual accountability and challenges what a student may view of ‘doing school’. Many students, it could be argued, have learned what it means to “do school” by either engaging in discussion or gaining enough inference from what others are discussing in class to participate adequately, or simply keep quiet during discussion.

There may be several strategies to help online students assimilate to “doing school” online. Per-

haps the most utilized strategy is to give student a pre-assessment evaluating certain skills that are needed to be a successful online student. Many universities now utilize some sort of instrument that asks students a variety of questions about their learning habits to find a “goodness of fit.” For example, the University of Georgia uses the Readiness for Education at a Distance Indicator (READI @ <http://goml.readi.info/>) which is a self-assessment in which the student evaluates him- or herself on a variety of indicators like: life factors, personal attributes, learning styles, reading rate and recall, technical competency, technical knowledge, and typing speed and accuracy. There may be other ways to address the issue of student readiness within online courses, including scaffolding student learning at the beginning of the class and providing assistance with establishing regular activities and other strategies mentioned in this chapter. Another potential powerful strategy is assigning student-student pairs or each student to a small group and requiring they participate in activities in which they form a bond or rely upon each other to complete course tasks. For example, you may ask groups to define expectations about group standards of behaviour or something a little more fun like identifying a group name, wiki, or mascot. All of these activities are socially binding acts that may help students from dropping out if they feel they have more connections and support for learning in online environments.

Co-Regulation

Navigating online teaching and learning, or becoming an efficient online teacher and/or online learner, requires that an individual is able to adequately use processes, strategies, and responses to plan and monitor his or her participation in pedagogical activity (Zimmerman, 2001, 1994). This concept, known as self-regulation, reflects those processes that occur at an individual level that play an important role in student academic achievement (Zimmerman, 1994). In many cases, online students are ill-prepared for online courses

or drop out of online courses due to their inability to regulate (i.e., plan or monitor) their own learning. Ironically, this is also related to the convenience myths/misconceptions of online teaching and learning—a teacher or student need not go to a bricks-and-mortar classroom at a prescribed time, one can learn anytime and anyplace. In reality, it is very difficult for some students to be self-regulated enough to complete a course online.

McCaslin and Hickey (2001) proposed, however, that co-regulation is a more appropriate concept when discussing regulation of the teaching and learning process within socio-cultural contexts from a Vygotskian perspective (Courtney, 2001). In reference to this position, Zimmerman (1986) stated that “self-regulation is not an idiosyncratic product of the child’s own discovery experiences; but rather, it is a culturally transmitted method for optimizing and controlling learning events” (p. 311). The processes of regulating teaching and learning does not fall simply on the isolated individual, but is shared between and among students and teachers. In this sense, the self-regulatory functions of the student are influenced by others within the socio-cultural environment (i.e., peers and the teacher), just as others’ self-regulatory functions are influenced by that individual student.

Another aspect of co-regulated learning is monitoring strategies. Self-monitoring strategies refer “to students’ efforts to observe themselves as they evaluate information about specific personal processes or actions that affect their learning and achievement in school” (Zimmerman & Paulsen, 1995, p. 14). Students who have effective self-monitoring strategies are able to evaluate their own progress towards an established goal, making appropriate strategy changes as they proceed to regulate their learning effectively (Zimmerman & Paulsen, 1995).

The ability to effectively monitor one’s own learning processes are also dependent upon a wide array of technical, social, and psychological variables (see Zimmerman & Paulsen, 1995). Let us briefly discuss self-monitoring of the writing process as an example. Writing the “old way,” in

other words before word processing was pretty rudimentary and in retrospect seems almost primitive. An individual first had to prepare quite thoroughly before writing, often generating a detailed outline and/or completing a rough draft in long hand, before moving to type the paper on a typewriter. There was a certain diligence required on the part of the individual for if a mistake was made, it could necessitate starting the entire process all over (unless your professor did not mind a lot of liquid paper). The process described was necessary because there were constraints associated with the technological tool that was utilized to write (i.e., typewriters...an electric one if you were lucky). The process, itself also served as a self-regulatory strategy that monitored the writing process. The invention and utilization of word processors has, however, altered the procedural script of writing used by students and, essentially, made obsolete a monitoring strategy used for writing.

There are three primary suggestions for faculty when teaching high quality online courses. First, it is important for faculty to be explicit about how to “do school” online and ways to assist in the co-regulation of student learning in your course. One promising practice in online courses is to keep the patterns of behavior or interactions similar throughout the duration of the course. For example, always ‘open’ online course discussions on Mondays and students are expected to have their points posted by Friday. Second, faculty should plan for activities to help students identify and address the ways in which there may be differences in how to “do school” in their online course. Faculty should also assist students in how they plan to work their online course requirement into their calendar; this is also referred to as an ‘orienting activity’ (see Olgren, 1998). Third, faculty should provide guidelines for activities and assessments that address both issues, rituals of participation and co-regulation, to help scaffold these skills throughout the duration of the course. Scaffolding simply means that the faculty member should provide a lot of assistance with these activities at the beginning of the course

and as the course progresses; the faculty member slowly withdraws that help as the student gains confidence and masters course material.

Administrative Support of Faculty

Quality online course delivery is contingent upon administrative support of faculty. Additionally “administrators need to understand their faculty population if they are to support faculty participation in [online teaching and learning]” (Schifter, 2004, p. 25). However, according to Jorge Gaytan (2009) while all valued online teaching and learning there was little agreement among deans, vice presidents for academic affairs, and administrators of distance learning at campuses regarding the organizational structures that would support online teaching and learning. It could be that online teaching and learning as a field has, traditionally, been focused upon the pedagogy of teaching and learning that takes place within online learning environments and contributes to institutional culture. Two important factors that face administrative support of faculty and delivering quality online courses and programs are adequate support for planning and faculty workload.

Adequate Support for Planning

Osika (2006) warns that there are many administrative issues that need to be addressed within and across institutions to provide support for online students and faculty beyond the borders of the virtual learning environment. The issue of adequate faculty support, however, is perhaps the most examined administrative issue in distance learning literature (see Ko & Rossen, 2001). Levy (2003) outlined critical factors for administrators to take into account when planning for online courses and/or programs; she proposed that planning be systematic and strategic. Levy (2003) stated that “the challenge to colleges in the 21st century is not to decide why they should have an online distance learning program, but to decide how to design and implement such a program” (p. 3).

Effective and innovative leadership plays an important role in the development and delivery of online course and programs (see Latchem & Hanna, 2001). Beaudoin (2003) stated that “any focused consideration of the dimension of leadership and its impact on the growth and apparent success of distance education at literally hundreds of institutions worldwide” has been largely absent from the literature (p. 3). There appear to be some disconnect, however, between the roles that faculty and administrators play in the development of quality online courses and programs and this disconnect is reflected recent studies on the topic. One of the first steps for administrators to support online students, faculty, and programs would be to understand the demands on online faculty when designing and planning for online courses and programs. Administrators should clarify, in discussions with their faculty, any misconceptions about developing and offering a high quality online course/program. For example, Gaytan (2009) found that there was a disconnect between administrators’ rhetoric and practice and that there was still, on the part of administrators, “an emphasis is on cost savings, remaining competitive, and delivery of information as opposed to instructional quality” (p. 69).

Howell, Williams, and Lindsay (2003) stated that there is a need to pose difficult questions about online programs, but a need to address those questions “from an informed perspective” (p. 1). As Gaytan (2009) found, there were many instances in which administrators and faculty differed in important ways when discussing online teaching and learning. For example, “while online education coordinators and faculty [in his study] were thinking about the ways to improve the quality of online education, academic administrators had other priorities such as being able to remain competitive” (Gaytan, 2009, p. 69). This illustrates a common assumption, on the part of institutional administrators, that online courses will address the need to service more students for the same costs, often by increasing the number of students within online courses (Concieção &

Baldor, 2009). As stated in the beginning of the chapter, there are also myths and misconceptions about online teaching and learning that may be held by both administrators and faculty. Assumptions, myths, and misconceptions need to be examined and discussed by administrators and faculty members within the context and characteristics (i.e., pedagogical alignment) of a particular course or program. This is a critical first step during the design and planning stage of online courses and programs. Administrative support of faculty for high quality online courses needs, however, to extend beyond support to encompass adequate planning (Osika, 2006).

Faculty Workload

One issue that has received some attention in the online teaching and learning literature has been that of faculty workload. Lehmann and Chamberlin (2009), for example, illustrate the number and variety of hats that online faculty wear when teaching a high quality online course: (1) teacher, (2) facilitator, (3) instructional technologist, (4) course designer, (5) writer, editor, and proofreader, (6) counselor and mediator, and (7) advisor and registrar. Wearing more hats, however, may not necessarily result in increased compensation for the online faculty member. For example, in Schifter's (2004) research surveying administrators about online teaching and learning issues, both found that there was little consistency with faculty compensation. Additionally, faculty may not be prepared to wear many of those hats and professional development, mentoring programs, or providing other models to those faculties may be critical (Blythe, 2001).

The complications and added workload for the online faculty member is debated in the research literature. Some researchers have found that more students in an online course increases workload due to more student-teacher interactions and/or more individual feedback on assessments, particularly if a pedagogical alignment is used for the course that is more student-centered (Matuga, 2005). Other

researchers, however, have found that placing additional students within an online course may not increase faculty workload substantially, especially if the online faculty member has previous online teaching experience or the course's pedagogical alignment is more teacher-centered and does not require a lot of student-teacher interaction and student monitoring (Anderson & Avery, 2008; DiBiase & Rademacher, 2005; Matuga, 2005). It is very important, however, to realize that many of the studies investigating faculty workload were comparison studies with face-to-face faculty. As stated in the introduction of this chapter, this premise may be flawed as we are not comparing apples-to-apples therefore, investigating faculty workload from a comparison perspective may not adequately reflect what an online faculty *does*.

Just as it may be more accurate to examine online teaching and learning as a cultural system, it may be necessary to redefine the roles, responsibilities, and what it means to be an online faculty member. The supposition that online faculty is treated differently at educational institutions, and this may be a threat to academic quality, has been a recurring theme in the research literature (Concieção & Baldor, 2009). Schifter (2004) found that faculty workload for those teaching online courses were not to consistent within and across institutions (Schifter, 2004). This has given rise to a trend at educational institutions of hiring online adjunct faculty to teach online courses (Puzziferro & Shelton, 2009). On the one hand, while this group of faculty may have highly specialized skills to teach online there may still be a perceived threat to the online quality of courses and programs. Regardless, the rise of the online adjunct faculty illustrates the need for an examination of knowledge and skills required to be an effective online faculty member and support from administration for quality online course delivery. It also necessitates the transformation of how we assess and evaluate effective online faculty, especially if we look at online learning environments as complex, cultural systems. A cornerstone of support for online faculty from

an administrative perspective should include support for the systematic assessment and evaluation of online courses with an eye toward continual improvement.

FUTURE RESEARCH DIRECTIONS

The last issue explored in this chapter, which of continual improvement, encompasses the various aspects for all the topics features highlighted in this chapter: pedagogical alignment, meaning making, rituals of participation, co-regulation, administrative support for faculty planning courses/programs, and faculty workload. The relationships between and among these different factors illuminate themselves to be reciprocal in nature through the process of continual improvement. It is in this sense that online teaching and learning contributes to the notion of cultural systems discussed at the beginning of the chapter.

Continual improvement is the act of reflecting on the effectiveness of pedagogical alignment within the context of the constraints and affordances of the online teaching and learning environment. Perhaps the most important component for continual improvement, for example, is pedagogical alignment which, as stated earlier, requires that instructional variables like student learning outcomes, learning activities, and assessment and evaluation practices, that support student success and learning, be selected with care during the planning process (Matuga, 2005). Pedagogical alignment provides a blueprint for continual improvement. However, continual improvement also mandates the re-visitation of pedagogical alignment during and after the course has been taught with the goal of perfecting the course with an eye towards assuring quality.

Sims and Jones (2002) proposed a three-phased model for continuous improvement in online classes that emphasizes the importance of pedagogical alignment and instructional design. They proposed that there be a “Pre-Delivery” phase in which the focus is on the functionality of the

newly designed course be peer evaluated. This could be by utilizing some of the peer-evaluation methods mentioned in this chapter. The second phase is that of an initial delivery, or enhancement stage, and the last stage is an ongoing delivery or course maintenance phase in which the course is modified based upon feedback from students and peers. This approach emphasizes a team approach to course design, evaluation, and redesign. This is also called within socio-cultural literature creating ‘communities of practice’. Sims and Jones (2002) outline that building shared understanding, establishing rituals of participation, and maintaining communication are all critical components of their continuous improvement model. Continuous improvement is by its definition, a dynamic process that examines those shared ideas of what is quality online teaching and learning and is essential for assuring quality.

CONCLUSION

As a review of the online teaching and learning research by Tallen-Runnels and colleagues (2006) illustrated, online teaching and learning can be and has been a field typically organized by following four categories: course environment, learners’ outcomes, learners’ characteristics, and institutional and administrative factors. There are two issues when designing online courses, according to Ternus et al, (2002), “The first is the quality of teaching tool and the second is the quality of learning that takes place. In this chapter we have presented a foundation for viewing some of these topics through the lens of cultural systems.”

Three common myths/misconceptions regarding online teaching and learning were presented at the beginning of this chapter to help frame the discussion presented. One last myth or misconception that was not highlighted in this paper is that online teaching and learning is less expensive than face-to-face teaching. Divorcing this myth from the comparison (apples to apples)

metaphor, this is a topic that was touched upon when the subject of administrative support of faculty was discussed, but not fully examined. Colleges and universities are pressured into developing online courses and programs, in essence, to meet economic shortfalls. However, as Levy (2003) stated “the challenge to colleges in the 21st century is not to decide why they should have an online distance learning program, but to decide how to design and implement such a program” (p. 3). The subject or relationship between how much a course/program cost and quality of learning within that course/program remains a very complex and difficult topic to frame within the topic of assuring quality.

The issue of assuring quality in online courses and programs is a multifaceted one that requires we look at the online teaching and learning environment with a fundamentally different lens, that as a complex, cultural system with unique affordances and constraints. While an exhaustive list is not presented here, important factors that influence the design of high impact online courses, make suggestions for faculty who are teaching online classes that ensure quality, impact administrative support of online faculty, and offer a potential model for continual improvement. All of these factors are aligned with the central premise of this chapter that assuring quality in online course delivery is a complicated communal activity focusing on the alignment of sound instructional features, meaning-making, working together with students to develop new ways ‘to do school’ online, recognition of faculty work, and continual improvement.

KEY TERMS AND DEFINITIONS

Assuring Quality: Online course delivery focusing on the alignment of sound instructional features, meaning-making, working together with students to develop new ways ‘to do school’ on-line, recognition of faculty work, and continual improvement.

Continuous Improvement: A dynamic process that examines those shared ideas of what is quality online teaching and learning and is essential for assuring quality.

Continual Improvement: The act of reflecting on the effectiveness of pedagogical alignment within the context of the constraints and affordances of the online teaching and learning environment.

Cultural Systems: Within online environments refers to understandings and meanings that are socially shared.

Evaluation: Includes examining the content, processes, impact and outcomes of on-line courses in order to improve the course quality.

High Impact Practices: Refers to educational experiences that are meaningful, require student action and participation, and that contribute to the life-long learning of the student.

On-line Teaching and Learning: Faculty-delivered instruction via the Internet or distance learning.

Self-Regulation: Refers to those processes that occur at an individual level that play an important role in student academic achievement.

A Study on Extensive Reading in Higher Education

Diana Presadă

Petroleum-Gas University of Ploiesti, Romania

Mihaela Badea

Petroleum-Gas University of Ploiesti, Romania

INTRODUCTION

There is a widely spread consensus among researchers and practising teachers that extensive reading programs are an important tool for teaching English as a second language. But, in spite of its tremendous contribution to the development of students' language skills, the difficulties entailed by the implementation and monitoring of such programs diminish teachers' enthusiasm about integrating them in the instructional process, especially in higher education.

As to university students, they tend to limit their reading activities to the topics of the syllabus, perceiving reading as a compulsory task that can ensure school success and not as a pleasant free-time activity. In other words, students are more interested in extrinsic rewards rather than in being intrinsically motivated readers. As Cambria & Guthrie (2010: 17) put it, 'students who read only for the reward of money, a grade or a future job are not the best readers', their major purpose being the reward itself and not learning. On the other hand, reading for enjoyment is a necessary but not sufficient condition to increase students' motivation for extensive reading. As the same authors point out (2010: 16), motivation includes 'the values, beliefs and behaviours surrounding reading for an individual. Some productive values and beliefs may lead to excitement, yet other values may lead to determine hard work.' This

determination, the two authors explain, consists in three factors that propel students to read, that is, interest, dedication and confidence, meaning the combination between reading for pleasure and a planned effort to reach the intended success.

Using the internet as a source for reading may help teachers develop students' intrinsic motivation within a well-organized reading program. It is a fact that students resort to the internet on a regular basis with various purposes: to communicate with their friends, to look for information they are interested in, to enjoy themselves etc. Whatever the reason, they will always turn to the internet as a first choice. Tempted by its tremendous advantages (rapidity, accessibility, huge stock of information etc.), most learners prefer doing their research more on the web and less in a traditional library. Under such circumstances, changing the internet into a tool for developing students' reading skills cannot but contribute to the success of an extensive reading program.

Taking into consideration the power of the internet to motivate students to read, the paper aims to find and evaluate students' attitude towards extensive reading. It also assesses the impact on students of a pilot program based on web resources analysing the results, identifying the difficulties involved by such a program, and trying to find solutions that may help the implementation of an extensive reading program into the curriculum of philological students in the future.

BACKGROUND

The general framework of the research on the implementation of an extensive reading program in higher education was provided by two categories of studies, their principles being applicable to reading no matter the medium, printed material or web resources.

The first category includes theories dealing with the effectiveness and positive effects of extensive reading on both cognitive and affective levels (Horst, 2005; Farrell, 2009; Nakanishi, 2015), whose synthesis of benefits is suggested by Nakanishi (2015: 9): ‘the freedom students have to choose books, the degree of autonomy enjoyed by the students, and the motivation to continue reading’. Moreover, the academic environment seems to be ideal for the application of an extensive reading program because, as Nakanishi (2015: 10) highlights, ‘the effect of extensive reading increases with older participants (...), who tend to learn language explicitly drawing on their analytical skills.’ The second category refers to the extensive reading activities described by Bamford & Day (2004) who offer a wide variety of useful ideas for an extensive reading program, including complex activities by means of which ‘teachers must take into account the effect of a class activity and a reading material not just on students’ ability to read, but on students’ self-images as readers, and on their feeling toward reading itself.’ (Day & Bamford, 1998: 166).

Generally, extensive reading of printed material or online resources implies the same cognitive processes as intensive reading does, presupposing an interactive model that consists in ‘constructing meaning from text through the use of both bottom-up and top-down strategies and skills’ (Şahin et al., 2014: 65, Nuttall, 1996). In other words, to successfully accomplish a reading activity, students need three types of competences at work: background knowledge to help them understand the possible meaning of the text, information about the distinguishing features of the reading texts (fictional, non-fictional etc.) and a good command of the target language system. In the

case of philology students, their ‘familiarity with the context’ and content is supplemented by their awareness of ‘literary devices, such as metaphors and flashbacks’. (Jacobs & Farrell, 2012: 15). In brief, as Nuttall shows (1996: 127, 128), extensive reading ‘can help readers enter the circle of growth’, which she calls ‘the virtual circle of the good reader’, on the grounds that it implies a multilateral and interrelated improvement connected with the reading speed, the capacity to understand ideas and a strong feeling of satisfaction while discovering the fictional world of the text.

Besides the characteristics of the reading process in general, the differences between intensive and extensive reading should also be considered when starting an extensive reading program. As shown in Table 1, what fundamentally separates extensive from intensive reading is that the former requires written material within students’ language competence, these texts being accessible, easy and enjoyable. Furthermore, students are stimulated to read what they want in their own time and as much as they can.

Table 1. Intensive vs. extensive reading

Intensive Reading	Extensive Reading
Reading for comprehension	Reading for pleasure
Students have to read	Students are motivated to read
100% comprehension of the text	Less than 100% comprehension
Word for word reading	Inferring the general meaning
Study of individual words and structures	Understanding sentences and discourse rules
Aid of the teacher in reading	Autonomous, independent reading
Reading above level	Reading according to level
Use of various comprehension strategies	Use of already acquired overall comprehension strategies
Use of dictionary for unfamiliar words and structures	Use of dictionary for vital words only
Short texts	Long texts
Reading done in classroom	Reading done outside the classroom
Teachers choose the reading material	Students select what to read

Due to the particular nature of extensive reading, it is essential that students get familiar with various techniques for inferring meaning and with the idea to accept overall comprehension instead of word-for-word understanding, specific to intensive reading. To achieve these goals, regular exercises done during the intensive reading and semi-extensive reading activities as a preparatory stage are necessary because they may form a solid basis for the development of the students' skills within an extensive reading program.

According to numerous researchers (Anderson, 2009; Grabe, 2009; Day, 2013), extensive reading represents a great opportunity for students to use the target language structures in various situational contexts and develop their vocabulary knowledge in view of the fact that they can 'meet the same lexis repeatedly in communicative contexts' (Nakanishi, 2015: 10, Grabe & Stoller, 2013). As to philology students, an extensive reading program would help them become proficient readers, an indispensable quality for their future career. Being proficient readers means meeting five parameters, as indicated by Coady & Huckin (1997: 228): 'immersion in meaningful texts, incidental language learning, integration of oral and written language, focus on meaning rather than form and the fostering of high intrinsic motivation'.

In such a context, the implementation of an extensive reading program based on web resources can help the educational process in higher education to shift from the traditional focus on the teacher to student centred methods 'by giving students more control of their own learning, for example, by students choosing what they will read; by students giving their own interpretation of what they read and bringing their own experiences, hopes and beliefs to the text and by students putting their own stamp on what they do while and after reading.' (Jacobs & Farrell, 2012: 3). Thus, extensive reading may pave the way for a qualitative educational change at academic level.

METHODOLOGY AND METHODS

To make students value reading outside the classroom, an extensive online reading program would be beneficial to adult learners, especially students in Philology, for the reason that it suits the cognitive processes required in an academic environment.

Piloting this program offered the possibility to see how intensive reading harmonises with extensive reading within a controlled approach whose final aim was to reinforce and develop students' English language skills.

Starting from the above-mentioned objectives, the following research questions were kept in mind:

- RQ1:** What are the major gains of an extensive reading program adopted at academic level?
- RQ2:** What drawbacks can such a program bring about in the educational process?
- RQ3:** To what extent can extensive online reading motivate students to become proficient readers?

PARTICIPANTS AND PROCEDURE

To put into practice an extensive reading program based on web resources in the University of Ploiesti, instructors constituted 2 groups of learners who volunteered to take part in the research. 64 undergraduate Philology students in the second year were involved, 38 specialising in Romanian and English and 26 in English and French. The program was based on volunteering because the Philology curriculum includes a variety of reading materials for the studied subjects and an extensive reading program would have meant a supplementary effort that not all students were willing to make.

The research consisted of 3 major stages with different targets: to examine students' reading experience and establish the list of online reading materials; to implement the extensive reading

program; to evaluate its effectiveness and set new strategies for the future.

During the initial stage a survey was administered to discover the participants' experiences, habits and attitudes towards reading in English. They had to answer several closed items to check their reading preferences and several open items focused on the reading time in English, their favourite writers, the difficulties encountered when reading and their perception of their own reading skills. It should be noted that the survey was very useful for orienting the reading list included in the program because it showed the kinds of texts mostly enjoyed. But to establish a coherent and efficient reading approach, it was necessary to identify the reading level of the students by means of a reading assessment test which was conducted at the end of the first semester of the academic year 2013-2014.

The results of the surveys enabled the preparation of the second stage that consisted in making the list of the online reading material. As freedom of choice is the basic criterion of a successful extensive reading program, students were encouraged to express their preferences in point of writers and types of reading texts. After identifying the students' reading tastes and levels, instructors had to establish a cohesive list of texts. It was necessary to do so because, as some sceptical researchers mentioned by Jacobs and Farrell (2012: 16) state, abusing the power of choice or adopting an 'anything goes attitude' to reading may be counter-productive.

The list contained non-fictional material (magazines and newspapers) and fictional prose (novels and short stories). The magazines and newspapers showed students' interests in topics like food, fashion, travelling, science, films etc., whereas the fictional texts, especially prose, referred to classical and modern writers (Emily Brönte, John Fowles, Vladimir Nabokov etc.) reflecting their desire not only to expand their knowledge about the issues studied in courses, but also to read other authors corresponding to their tastes and curiosity.

As students had different levels of competence in reading, the list also included graded fictional materials although some researchers think that 'the use of graded readers in EFL is controversial because some believe that they are not authentic' (Day et al., 2013). Being of real value as they encourage students to read according to their own level, graded materials were intended for intermediate and upper-intermediate learners.

In addition to students' preferences, several basic principles discussed in literature (Nuttall, 1982, Hill, 1997, Bamford & Day, 2004) were taken into consideration when making the reading list. The reading ease criterion (texts within students' reading level) guided the choice of texts whereas the variety of topics and genres, facilitated by the huge possibilities of the internet, could suit all learners' needs. To stimulate students' interest in reading, as Nuttall points out (1982, 171), texts 'should not smell of the classroom', their value consisting not in the number, but in the purpose for which it was established. Even if the reading list included a limited number of titles, especially at the same language level, as Hill (1997) notes, this may turn into an advantage because 'students will soon read similar titles and they can then share their experiences together' if encouraged during the monitoring activity held by the teacher.

To persuade students to participate in the program a semi-extensive reading activity was performed in the first week of the second semester, during which the whole class had to read the same online material which was a short story corresponding to the average reading level of the class and to their interests. The familiarization stage being achieved, students were invited to enrol in a program dedicated to reading internet-based resources outside the classroom. The students that signed up (64) were given the weekly reading target: three one-page newspaper or magazine articles and one book. Setting the reading target is an important step to be taken because, as the majority of the researchers claim, no progress can be achieved in the absence of a well-defined number of reading materials. This target should be

Table 2. Sample vocabulary log

understood 'in terms of the level and the number of books' (Hill, 1997) to be read each week as long as the program lasts. It should be mentioned that, to avoid wasting time when searching for the online material, students were provided with numerous links to access the texts included in the reading list.

To monitor their reading activity, a series of tasks were also conceived for the participants to complete by the end of each week. The tasks were gradual ranging from simple to medium and complex requirements. The first category comprised poster reports and story webs which students had to display on the walls in the classroom, focusing on characters, relationships and actions. The second one included vocabulary and plot logs for which the following vocabulary pattern was suggested as in Table 2:

The most complex and creative tasks such as book/article reports/reviews and 'The book/article and me' reports belonged to the third category. The 'me report' activity aimed at students' personal responses, as they had to explain their impression of what they had read and what new things they had learnt.

As concerns the post-implementation stage of the extensive online reading program, this was done in the last week of the second semester and consisted in a report on the advantages and disadvantages of the program, indicating its impact on the students and their attitude towards reading outside the classroom.

RESULTS AND DISCUSSIONS

The implementation of the extensive online reading program was oriented by the initial survey

administered to the students. According to the findings, a percentage of 57.69 students spend each week between 0 and 2 hours reading for pleasure in English (printed or electronic material), whereas 38.46% of them indicated between 3 and 5 hours. The surprising fact is that only 3.85% of the students dedicate more than 10 hours a week to reading in their free time.

The relatively high percentage of students who spend a short period of time reading for enjoyment is quite worrying because their philological profile requires not only imposed but also free reading as a way to improve language acquisition. Students' attitude towards reading may derive from the fact that they tend to consider extra-curriculum requirements to be time-consuming and useless. This demonstrates that they base their motivation on extrinsic rewards such as grades, which, as Cambria & Guthrie (2010: 17) explain, 'represent their quality as a student and as a reader. Being a high achiever is a symbol of how they are doing. A high grade is an icon of success and these students strive to feel successful.' Such a view of reading is also supported by their answers to the questions meant to find if they enjoy reading in English, the difficulties they encounter and what their favourite writers are. Almost two thirds of the respondents are fond of reading in English, but only the writers they study. As concerns the difficulties they have, most of them refer to vocabulary problems which hinder overall comprehension, this revealing that students are accustomed with intensive and not with extensive reading.

Another objective of the survey was to discover students' preferences regarding the reading text types. Almost 60% of the students like reading fiction, which is in accordance with the answers to the previous questions reflecting their interest in literature as part of the syllabus. As to their favourite genres, 73.08% mentioned prose and only 15.38% drama, respectively 11.54% poetry. These results may be explained by their perception of prose as more interesting and reader-friendly than drama and especially poetry. With respect to the non-literary texts preferred by the

respondents, 30.43% chose science books while 69.57% ticked magazines and newspapers. A possible justification for this high percentage is that reading newspapers and magazines makes students feel connected to real life because the various subject areas they find here respond to their needs and interests.

Interesting viewpoints were also shown by students' opinions of reading in English as a way of improving language abilities. Although all of them gave a favourable answer, they confuse extensive reading skills with the ability to speak, translate and pronounce correctly. Nevertheless, some students (38.63%) mentioned consolidation of vocabulary and grammatical structures among the benefits of reading in English. This percentage together with the one of participants who spend 3 to 5 hours a week reading extensively shows awareness of the advantages of reading outside the classroom.

In connection with students' English reading abilities, more than half believe that they are not good readers, the most frequent reasons being linked to poor vocabulary and a loaded timetable that does not allow reading outside the classroom. The overloaded bibliography they are required to study for regular classes does not give them time to read for pleasure. However, they admit that reading plays an important part in their lives, emphasising its informative role and the enrichment of their cultural background.

As to the students' final reports, their highly positive opinions on the program are worth analysing. First, students stated that they liked reading online materials outside the classroom considering it as useful as the compulsory reading syllabus. Second, they pointed out that they could read independently, enjoying the freedom to choose the most interesting articles and books. They also appreciated that they were able to read whenever and wherever they wanted to and at their individual reading speed. Choosing materials in accordance with their level eliminated the vocabulary difficulties that might have hindered the rhythm of the reading. The third aspect students indicated was the

chance to suit the reading materials to their levels, which made reading easier and more captivating than their former reading style. At the same time, inferring meaning from context instead of using the dictionary was recognized as a great step forward towards fluent reading. Briefly speaking, participants' answers show that they appreciate the benefits of extensive reading, benefits which, in Nuttall's terms, mean 'speed, enjoyment and comprehension' (1996: 128). Learners' opinions reflect a new attitude to reading, overcoming their former belief that school success depends only on reading what teachers indicate. Such a prejudice might be due to the authoritarian university teaching style according to which the teacher is the main decision factor in the learning process, irrespective of the subject.

Another advantage was that, by reading a large variety of online texts, participants had the opportunity to come across a great number of new words in different contexts, which led to a significant development of their vocabulary. In other words, by 'multiple exposures to new words' students can 'learn a large amount of new words' (Grabe, Stoller, 2013: 53). Finally, 'by reading the same patterns of letters, words, combinations of words again and again students process them more quickly and accurately and thus develop a sight vocabulary (words that are recognized automatically)' (Day et al., 2013). Students' perception somehow contradicts the findings reported by Tudor and Hafiz (1989, 1990) in their studies who reached the conclusion that extensive reading cannot be regarded as the best way of improving vocabulary.

In addition, learners pointed out that extensive reading helped them reinforce and develop structures already studied as well as other language abilities, their opinions reflecting what researchers mean by 'spread of effect', that is, development of interconnected skills such as 'writing, speaking and control over syntax' (Day and Bamford, 1998: 33). Although the cognitive mechanisms linking reading to other skills are not completely understood, as Hoey (2005) and Nuttall (1996)

state, it stands to reason that the more students are exposed to the new vocabulary and grammatical structures, the more competent they become in speaking and writing.

Finally, students admitted that extensive reading enabled them to develop their general knowledge about the world, to make connections with other fields of interest and to adopt new perspectives on life. This demonstrates the passage from the former extrinsic to intrinsic motivation which, in Farrell's terms, means that they internalised the idea that extensive reading is a way to 'develop themselves both personally and professionally' (Farrell, 2009: 88).

SOLUTIONS AND RECOMMENDATIONS

Students' reports also contained several disadvantages of the extensive online reading program, which should be considered when implementing it on a large-scale. Thus, they complained of the lack of time for extra-reading, mentioning their loaded timetable as well as the amount of compulsory reading as part of the syllabus. They also incriminated the fact that some links were accessed with difficulty or they wasted too much time when searching through different databases.

The dysfunctions of the pilot program as suggested by students will be of great help in improving the implementation of a future one. A possible way to solve the problem of the overloaded reading tasks could consist in a rigorous selection of the material and in harmonising the compulsory reading with the free time activities. This could be achieved if the extensive reading program becomes part of the curriculum within a reading course based on the principle of alternating intensive reading with extensive reading activities. Besides reading in quantity and regularly, the key to success is to provide students with time for doing it. According to some researchers, 'Reluctant readers simply do not read outside of the classroom, so if we truly believe that students must interact

with the text regularly, then our schedules need to be altered to provide time for that during the school day.' (Jacobs, Farrell, 2012: 2). As to the difficulties encountered when accessing the online material, a good idea would be to precede the reading activities by a web-based tutorial to help students search on web catalogues and through databases more efficiently.

FUTURE RESEARCH DIRECTIONS

Although the pilot extensive reading program based on web resources had a very good impact on students, its implementation on a large-scale implies a larger team of teachers that will have to re-analyse the basic findings of the present program in order to replicate it.

As motivating students for reading by means of every resource available, including the internet, is an important objective of any language teacher, the study can develop into a larger analysis of the role of technology in developing reading skills and in making their reading experience most productive.

Another challenging perspective of research would be the implementation of an extensive reading program taking into account the combination between printed materials and internet-based resources. Such a complex program may offer both students and teachers new educational opportunities to explore. Moreover, teachers can conduct specific research to compare the role of printed materials and internet-based resources in developing students' reading skills.

CONCLUSION

The implementation of an extensive online reading program at academic level proved to be beneficial for the development of the skills required by the specificity of philological studies. The success of the study in stimulating students to read for pleasure was demonstrated by the feedback provided in the final stage. It is worth mentioning that, in

spite of an overloaded timetable, the majority of the students volunteered to take part in an activity that was different from their daily routine, even if that required additional effort and work. Thanks to their openness and motivation, the implementation of the program unfolded without serious problems and obstacles. The monitoring process revealed that they got more and more seriously involved in doing their reading-related tasks, meeting deadlines and sharing opinions on the books they read.

One of the greatest gains of extensive reading is the formation of a lifetime habit according to which reading is perceived as a personal experience and interaction with the reading material, irrespective of its kind, printed or electronic, corresponding to varied purposes people may have in life such as to entertain, to get information, to relax etc. In addition, extensive reading focuses the teaching-learning process on students, enhancing the responsibility for their personal growth.

In conclusion, the successful design, development and implementation of an extensive reading program in higher education may contribute to the creation of a positive environment that will lead to the development of the learning and teaching process in EFL.

KEY TERMS AND DEFINITIONS

Extensive Reading: Reading in quantity, outside the classroom, to get a general understanding of a text.

Fictional Texts: Types of texts including poems, short stories, novels and plays.

Graded Reading: Reading according to the students' language level.

Intensive Reading: Reading in the classroom in order to get a detailed understanding of a text.

Language Motivation: Various factors, such as willingness, desires and attitudes, determining students to learn a second language.

Non-Fictional Texts: Types of texts including newspapers, magazines, textbooks etc.

Online Library: List of links to download reading material.

Reading Level: The level at which a reader understands a text.

Technology Policies and Practices in Higher Education

Kelly McKenna

Colorado State University, USA

INTRODUCTION

Teacher preparation classrooms are filled with digital learners, and as educators, we encourage ideas of integrating technology into their future content and pedagogy. The U.S. Department of Education Enhancing Education Through Technology Act of 2001 requires the integration of technology into elementary and secondary education, so teacher educators should be preparing their preservice teachers for integration in their future content and pedagogy. As educators we know teachers teach how they were taught, so effective use of available technology needs to be modeled for preservice teachers in order to permeate their future teaching of our youth. So, what classroom technology policies and practices are education classes actually modeling for their learners? For optimal learning and to effectively prepare preservice teachers for teaching in a digital world, teacher educators should be encouraging them to utilize the devices at their disposal.

BACKGROUND

Technology is an integral component of life as we know it, and many students have mobile technology devices available to them. To meet learners where they are, educators must discontinue the use of outdated teaching methods and embrace a digital world (Rossing, 2012). But, out of fear that students may not be focusing on the instruction, educators are banning the use of smart devices in their classrooms. Smart phones are used by indi-

viduals in the workplace for a variety of purposes, so “why do we prohibit students from using these devices in the place where they do their own daily work?” (Hill, 2011, p. 22). Students should be encouraged to utilize the devices at their disposal to improve class participation, investigation, activities, and creativity. The real advantage of using smart phones in education comes when they are no longer supplemental, but essential components in the learning process (Hill, 2011). By utilizing the devices that are a part of their everyday lives, students have the ability to continue gathering information and gaining knowledge outside of school. Integrating technology that is utilized by today’s learners’ in their everyday lives has the potential to revolutionize formal education (Peluso, 2012).

Technology integration in education refers to the utilization of technology to promote teaching and learning. By meeting students where they are in respect to technology, educators can create more learner-centered instruction, solving the challenges of students’ needs and desires to learn differently (McCaffrey, 2011). The inclusion of technology in teaching and learning modifies the current teaching paradigm and empowers students through hands-on learning. By integrating technology into pedagogy, educators can engage students like never before and cultivate deep, meaningful learning (McCaffery, 2011). When mobile devices are integrated into education, students’ learning can be extended beyond the boundaries of the classroom; “students with these devices can go any place and anywhere to get their information, learning from the palms of their hands” (Hill,

2011, p. 24). But, for many teachers, technology use in the classroom is an intimidating prospect; the ability to effectively integrate technology into the existing structure of teaching is no easy task.

Teachers are the key to effective technology integration; in order to transform their teaching paradigms it is imperative preservice teachers learn how to integrate technology (Bitner & Bitner, 2002). Instructing preservice teachers on effective technology integration can lead to teacher buy-in and the establishment of technology enriched curriculum (Hogue, 2013). Although preservice teachers are often digital learners and may be comfortable working with technology, they are frequently not taught how to integrate it into their pedagogy. Often “models of teaching based on their own experiences as students do not include the integration of technology into instruction” (Rosenfeld & Martinez-Pons, 2005, p. 146). Unfortunately, teachers have limited access to examples of effective technology integration after which to pattern their teaching (Bitner & Bitner, 2002). Rosenfeld and Martinez-Pons posit that teacher education programs often “focus on how to use technology rather than on how to teach with technology and integrate it into everyday teaching” (2005, p. 146). By observing their peers integrating technology and incorporating tools, teachers can be encouraged to apply the practices to their pedagogy (Hogue, 2013).

Technology education is a requisite for today’s learners to be prepared for leadership in a digital world. In spite of the Department of Education’s mandate to integrate technology into K-12 education and the International Society for Technology in Education’s (ISTE) emphasis on infiltrating teacher preparation programs in order to accomplish effective incorporation of technology into teaching and learning (ISTE, n.d.), teacher preparation continues to be overlooked (Bitner & Bitner, 2002). Although preservice teachers may be comfortable working with technology, models for integrating it into their pedagogy is lacking. Effective preservice teaching prototypes of technology integration need to be modeled in order to

succeed in achieving successful implementation in K-12 education.

H

MAIN FOCUS OF THE ARTICLE

The purpose of this study was to reveal the technology policies and practices being modeled for preservice teachers in their teacher preparation curriculum. The research sought to answer the following research questions:

- What classroom technology policies are education classes modeling for their learners?
- Are teacher educators encouraging the use of smart devices for learning in their teacher preparation courses?
- Are teacher educators effectively demonstrating personal technology integration to preservice teachers?
- What technology integration practices are educators modeling in their teacher preparation courses?

The study was comprised of faculty who are instructors of teacher preparation courses at a teaching intensive university in the Rocky Mountain region. The sample consisting of 26 teacher preparation instructors was purposeful, as the intent of the study was to gather information about how teacher educators are modeling technology utilization and policies for their preservice teachers.

Syllabi for teacher preparation courses are collected and archived each semester. The researcher was granted access to the Fall 2014 syllabi for teacher education courses for the purpose of this study. In total, 84 syllabi were reviewed for this study. Also, a 13 question survey was sent to all 26 faculty of teacher preparation courses via their university email. The survey consisted of primarily open-ended questions regarding technology policies and technology integration in teacher preparation courses (see Appendix). Some sample questions were:

- If a policy regarding students' use of technology during class time has been communicated, what are the details of the policy?
- Do you integrate technology into your teaching?
- What is the best way to teach preservice teachers about TPACK (Technological, Pedagogical, and Content Knowledge)?

The initial data was collected by reviewing archived syllabi for teacher preparation courses. Following review of the syllabi from all teacher preparation courses, a questionnaire was sent out to all instructors of these courses via SurveyMonkey.

Descriptive analysis was employed to analyze data from the archived syllabi. The syllabi were reviewed for the presence of explicitly stated technology policies regarding personal technology use during class time. The qualitative data collected from the open-ended questions in the survey were analyzed and coded, and themes from the open-ended questions were examined. The analysis was comprised of an iterative process through which patterns in the data emerged (Creswell, 2014). Following coding of the responses and emergence of themes, the larger meaning, or interpretation, of the qualitative data was conceptualized (Creswell, 2013). Credibility issues were addressed by using triangulation, and the incorporation of multiple methods of data collection for comparison bolstered the internal validity and reliability of the research (Merriam, 1998). Analysis of the data showed the findings made sense through consistency and dependability, thus strengthening the reliability of the study (Merriam, 1998). The process utilized in this research allowed for a holistic analysis of the data.

FINDINGS AND DISCUSSION

There are faculty in the School of Teacher Education who, based on the data, appear to be interested in technology integration. They recognize the need

for preservice teachers to learn how to infuse their pedagogy with technology enhanced teaching as divulged in the literature. Some are even modeling technology integration, "there are a lot of us... actively modeling the infusion of technology into [our] courses. It's particularly important in Geography, with all of the cool geospatial tools now available". However, the majority of faculty seem to struggle utilizing technology in their own teaching and allowing students to practice mobile technology in their classes. As one faculty response indicated, "continuing professional development in the inclusion of technology and pedagogy would be helpful." Data collected from syllabi and surveys illustrated the lack of technology integration modeled in teacher preparation courses and the deficiency in faculty knowledge regarding technology enhanced teaching and learning.

Syllabi from the teacher education courses offered in the fall of 2014 were collected for the research. Any reference made regarding the use of personal technology use during class was noted. Of the 84 syllabi reviewed, 38 (45%) included some policy regarding the use of personal technology (including: cell phones, smart phones, iPods, and pagers), and 46 (55%) made no reference. The education courses were in Culture Linguistics Diverse Education, Elementary Education Early Childhood, Elementary Education, Foundations of Education, and Reading.

For the most part, the use of cell/smart phones was prohibited in courses that included a technology policy. In some cases, no electronic devices were permitted to be used during class time. And, many syllabi required that cell/smart phones not be visible, but put away. Only one syllabus acknowledged the use of a smart phone for learning purposes:

- "Using a cell phone or text messaging during class is the ultimate demonstration of disrespect for your fellow classmates and instructor. However you are invited to use them for classroom and learning purposes."

The majority of policies stated that the use of cell/smart phones during class was either unacceptable or not tolerated. In addition, ten syllabi included a penalty in the students' grade if cell/smart phones were used in class:

- "Put cell phone away during class time and during the tutoring time—cell phones that are visible will result in loss of points."
- "The following criteria will be used for earning the full 4 points for each class session: Cell phones are put away and visible only during break times."
- "Cell Phone Policy: Please turn cell phones off upon entering the classroom and leave them off until the class is completed. Using a cell phone or text messaging during class is the ultimate demonstration of disrespect for your classmates and instructor. Violation of this policy will result in loss of participation points."

Included in the syllabi containing a technology policy were three that banned the use of any electronic devices (including laptops and computers), a representative sample was:

- "Electronic and other etiquette:... Please do not use personal electronic devices such as laptops, netbooks, smartphones, iPods, cell phones, etc., in this class, or you risk losing points from your professionalism & participation grade."

Eight included verbiage that required cell phones not be visible during class time:

- "You should keep your portable electronic devices in your backpack or purse during class. Your personal electronic devices should not be on your desks."

The survey consisting of 13 questions was sent to 26 teacher education instructors at the

start of the spring semester and was completed by 17 individuals. Half of the 12 instructors who do not include a technology policy in their syllabi stated that they have communicated a policy in their classes. For the most part these policies, not included in syllabi, prohibited the use of cell/smart phones for texting or talking during class, but allowed students to have them. One instructor encouraged the use of these devices:

- "I have asked students to keep their phones handy so they can 'hitchhike' or look up something about anything that is going on in class. I want them to see google as a central classroom tool during discussions".

One unique response by an instructor stated that if he/she sees a student on their phone, he/she will:

- "share with them the research that shows their phones have control over them, they don't choose when to look. That means put it where you cannot see or hear it".

Question six of the survey asked instructors to explain the reason for their policy or lack of one. One instructor who does not have a policy regarding technology in the class shared the following:

- "Are students surfing during class? Yes – Periodically, but I do not consider this to be such an issue that I need to create a policy. Finally if I do see students surfing then I have to ask myself, 'What can I do differently to better engage students in the learning process?' I see that as a more appropriate response as opposed to saying you cannot do this and failing to take any personal ownership in contributing to the situation."

Two instructors referenced the current digital age when answering this same question:

- “It’s the 21st century and people have multiple ways of learning. I’m trying to make use of technology as an asset, not a deterrent. I really don’t understand faculty who don’t allow computers for note-taking in their classes. In 2015??”
- I think we should be moving toward integrating and inviting mobile tech right into the classroom. The more we assume it is a distraction, the more we are teaching in the previous century (or even the one before that). Larry Cuban’s book ‘How Teachers Taught’ shows clearly how our profession is unreasonably conservative about what counts as appropriate classroom behavior, and specifically what counts as ‘attention’. The research on classroom attentiveness, on-task behaviors, and so on suggest we should be rolling with the current technology instead of trying to push back against it.”

Technology integration was also covered in the survey. All of the respondents stated that they incorporate technology into their teaching. PowerPoint, videos and BlackBoard (the learning management system employed by the university) were the most common technology tools listed for how instructors integrate technology. However, 10 of the 15 respondents to the question, describe your knowledge of Technological, Pedagogical and Content Knowledge (TPACK), were unfamiliar with it and only five of 14 had ideas for how to teach their preservice teachers about TPACK.

- “By using the tools that are most used and popular. If we show them how the most popular tools can be involved in learning and teaching, we can claim relevance.”
- “Good practices should be included in all college level instruction. Not just one time in a separate class. Since that’s impossible, then all education related coursework

should integrate technology effectively and for the sole purpose of improving student learning. If preservice teachers are trained in how students learn, then in their education courses and methods courses as they learn methods for teaching their topic, then technology would be part of this training so that they learn how to evaluate how the technology is helping them teach their students. Technology changes so rapidly that teaching specific uses, is only somewhat helpful in the very near future. Technology is just another tool for teaching and should be an integral part of the coursework. Research has demonstrated that teaching skills out of context, is difficult if not impossible to transfer.”

When asked about the SAMR Model (Substitution, Augmentation, Modification, Redefinition), only two instructors were familiar with it and three were able to explain where they felt their teaching with technology examples fell on the scale.

- “I would say mostly augmentation... I use YouTube for example, to make my face-to-face feedback asynchronous (not really face to face, I guess), but it is a powerful way to reach students on their own time.”
- “R-Redefine. There are several things that I can do in my classes that were impossible 10 years ago.”

With few exceptions faculty at this teaching intensive university are failing to establish the relationship between technology integration and teacher preparation that is established throughout the literature. As one faculty noted, “we as university instructors are overwhelmed with administrative technology applications, when we should be focused on teaching applications, both in what we teach and in how we teach”. Fortunately there are those exceptions who feel that “I always have more to learn!”

FURTHER RESEARCH DIRECTIONS

In spite of the emphasis on combining technology into content and pedagogy and the availability of smart devices, teacher preparation programs are failing to model integration for their students. This study focused on one teaching intensive university. Further research exploring additional teacher education programs and their policies and practices may be beneficial in discovering how prevalent this problem may be. In addition, further research may identify a program effectively modeling smart device integration into the curriculum. An exemplar might further cement the need for showcasing the integration of smart devices in teaching and learning and its impact for preservice teachers' ultimate adoption.

CONCLUSION

The purpose of this study was to discover the personal technology policies and technology practices currently being modeled in teacher preparation courses. The data collected highlighted the technology policies being modeled for preservice teachers (research question one). The syllabi and surveys collected for this research established that not only are teacher preparation courses failing to incorporate personal technology, they are going so far as to restrict its use in the classroom. Only a minimal number of instructors at this teaching intensive university are encouraging their preservice teachers to utilize smart devices in the classroom (research question two). A few instructors are familiar with successful technology practices and are modeling smart device integration in their courses (research question three). Technology is an integral component of life as we know it and many portable electronic devices now have access to a plethora of information via the internet or various applications. This opportunity for learning should be recognized and utilized. Currently minimal technology (PowerPoint, videos, Black-

Board) is being demonstrated in the curriculum preservice teachers undertake (research question four). The integration of technology is one of the standards in K-12 education where our preservice teachers intend to educate, so preservice teachers need to have successful examples of technology integration after which to model their own teaching. Modeling effective technology policies and practices are imperative for preservice teachers to learn the practice of technology integration and later assimilate it into their classrooms (Bitner & Bitner, 2002) (research question five). This study aimed to highlight the comprehensive influence on digital learners when preservice teachers are successfully prepared for the allowance and incorporation of the technology readily available to their future students.

KEY TERMS AND DEFINITIONS

Learning Management System (LMS): The software system used for the delivery of courses online.

Mobile Learning: The use of personal electronic devices for the purposes of education. These devices include: handheld devices, tablets, and smart phones, or any other devices that allow for the learner to be mobile.

Preservice Teacher: Students who are currently in an educational program studying to become teachers. These students have not yet met the requirements needed to be certified teachers.

Smart Phone: A cellular phone containing many of the elements available on a computer. Often these devices have access to the internet.

Teacher Preparation Program: An approved course of study that meets the requirements necessary for certification.

Technological, Pedagogical, and Content Knowledge (TPACK): The framework required for effective instruction. TPACK is the integration of a teachers knowledge in the areas of technology, pedagogy, and content.

Technology Integration: Technology integration in education refers to the utilization of technology to promote teaching and learning.

H

APPENDIX

Questionnaire

1. List the programs in which you teach (EDF, ET, ELED, etc.).
2. Do you have an explicitly stated policy regarding students' use of technology during class time?
3. If you do have an explicitly stated policy regarding students' use of technology during class time, what does it state and where can it be found?
4. If you do not have an explicitly stated policy, have you ever communicated a policy regarding students' use of technology during class time?
5. If a policy regarding students' use of technology during class time has been communicated what are the details of the policy?
6. Please explain the reason for your policy or the lack of one.
7. Do you integrate technology into your teaching?
8. If yes, how do you integrate technology?
9. Describe your knowledge of TPACK (Technological, Pedagogical and Content Knowledge)?
10. What is the best way to teach pre-service teachers about TPACK?
11. Are you familiar with the SAMR Model (Substitution, Augmentation, Modification, Redefinition Model)? Please explain.
12. If you integrate technology into your teaching where on the SAMR Model do your lessons typically fall? Please explain.
13. Is there any additional information regarding technology policies and instructional modeling you would like to share?

The University–Industry Collaboration

Marcello Fernandes Chedid
University of Aveiro, Portugal

Leonor Teixeira
University of Aveiro, Portugal

INTRODUCTION

The collaborations between academia and industry - University-Industry Collaboration (UIC) - may occur according to different formats (multiple types) and recently have increased based on the third mission of the universities – knowledge transfer between university and external actors. This relationship offers advantages to both entities, addressing global challenges to their mutual benefit as well as benefits to society. Both university and industry recognize the potential of UIC relationship. Nevertheless, this relationship is complex and often appear threatening to both the university and industry through value and goals conflicts. The major reason for this complexity is that the collaboration between partners with different models of organization and culture needs a considerable management effort in order to be successful.

Despite the relevance of the theme, the studies in this area neither explain the various complexities associated with this relationship, nor present recommendations of improvement for the process (Santoro & Bierly, 2006).

In order to achieve success in this relationship, it is important the understanding of three drivers which are part of UIC, i.e., the motivation for collaboration, the channel of interaction and outcome and benefits of collaboration. Their understanding allows to mitigate barriers, overcome the differences, create an environment of trust and commitment (Kauppila, Mursula, Harkonen, &

Kujala, 2015) and consequently achieve success of the UIC.

This chapter aims to address these three main drivers of this relationship based on literature review.

BACKGROUND: THE UNIVERSITY - INDUSTRY COLLABORATION

Since the end of last century, factors such as the globalization, the growing competition and the rapid technological advances have transformed the complex business environment with impact on life cycles of processes, products and services (Kauppila et al., 2015; Mendes, Nunes, & Sequeira, 2012). This scenario forced the companies to find partners to face the new challenges, representing the University-Industry Collaboration (UIC) relationship a key resource for innovation (Lee, 2000), for promotion of technological change (Cohen, Nelson, & Walsh, 2002; Freitas, Geuna, & Rossi, 2013; Lee, 2000; Mansfield & Lee, 1996) and for promotion of higher productivity and greater economic growth (Freitas et al., 2013).

For universities, this relationship also became important, as with better awareness of the business value of its work and its research, universities have shown more interest in the marketing of their products (Santoro & Bierly, 2006). So, in addition, to contributing to the better training of their students, the UIC can provide to universities access to expertise that they do not have and

Figure 1. Types of University - industry collaboration

that is only possible with direct experience with companies (Ankrah & AL-Tabbaa, 2015).

In fact, both the university, and the industry recognize the potential of UIC relationship. Nevertheless, this relationship is complex and often appears threatening to both the university and industry through value and goal conflicts. The key challenge is the understanding of the organizational form of the other partner. As soon as each institution understands the needs of the other, a large number of opportunities will exist (Sherwood, Robinson, & Butts, 2011; Wallin, Isaksson, Larsson, & Elfström, 2014; Wright, 2008).

Universities and industries have different objectives, focus and ways of working, which represents some barriers to the UIC (Sherwood et al., 2011). One of the barriers faced in this relationship is the difference of views with respect to the deadline for execution of works. Universities have a long-term vision, while industries work with a short-term vision. The time frames are different (Pertuzé, Calder, Greitzer, & Lucas, 2010). Another important barrier highlighted by some

authors refers to existing divergence between what is developed by the researchers in universities and the real needs or expectations of the industries (Franco & Haase, 2015) which sometimes are completely disconnected or opposed to seeking industries (Arza, 2010).

According to Santoro and Bierly (2006), academic researchers have not adequately studied many of the complexities associated with this relationship and thus have not been able to provide insightful recommendations to improve the process. Franco and Haase (2015) complement with the information that a great number of investigations is concentrated on the academic side of UIC and attention is mostly paid to the individual researchers.

Regarding the type of collaboration between university and industry, it can be established according to different approaches, having different types of classification (Figure 1).

Generally, UIC is associated with the level of involvement of organizations and type of resources that are used, and the relationship include components such as problem solving, technology

development, ideas testing or knowledge generation (Perkmann & Walsh, 2009).

According to Nilsson et al. (2010), the different types of collaborations, sometimes occur simultaneously and in other cases one type is dependent on another.

In this sense, UIC relationships can be classified as formal or informal (Hagedoorn, Link, & Vonortas, 2000; Nilsson et al., 2010; Polt, Rammer, Gassler, Schibany, & Schartinger, 2001), and as short-term or long-term (Bruneel, D'Este, & Salter, 2010; Wallin et al., 2014). On the basis of its character the informal relationships are not much discussed or known (Hagedoorn et al., 2000), and usually do not require a formalized contract. This type of UIC relationship is, normally, a short-term relationship. On the other hand, the formal relationships require formalized agreements and generally are classified as a long-term relationship (Bruneel et al., 2010) and therefore have a better chance for success (Lee, 2000). Verheugen and Potocnik (2005) suggests that a long-term relationship demonstrate commitment, leading to good results, mutual understanding and respect.

UIC can be low intensity or high intensity (Perkmann & Walsh, 2007, 2009), being differentiated according to the intensity of contacts and activities demanded by the relationship. Finally UIC can be institutional or personal (Freitas et al., 2013; Verheugen & Potocnik, 2005). The type of institutional relationship involves the structure of the university, while the personal mode refers to the direct contract between firms and researchers at the university.

THE MAIN DRIVERS OF UNIVERSITY - INDUSTRY COLLABORATION RELATIONSHIP

In order to achieve success in UIC relationship, it is important the understanding of its three main drivers, i.e., the motivation for collaboration, the channel of interaction and the outcome and benefits of the collaboration. The understanding of

these drivers and their proper articulation, allows to mitigate barriers, overcomes the differences, creates an environment of trust and commitment (Kauppila et al., 2015) and consequently achieve the desired success of the UIC.

According to the several literature reviewed, the Table 1 presents a complete information identified concerning to these three drivers – motivations, channels and outcomes – in the context of UIC. It is also identified the information of which is the focus (actor) of the articles, i.e., on the universities (U), industries (I) or both (U/I).

Motivations of Interaction

The motivations are internal and external factors that stimulate to attain a goal, they are different for universities and industries (Ankrah & AL-Tabbaa, 2015) and it play an important role in the achievement of results (Lee, 2000), as well as in determining the type of channel to be used in the UIC.

Universities and industries seek through the UIC, to have access to resources, skills and abilities that are currently limited to one of the entities (Wallin et al., 2014; Wright, 2008). The characteristics of the university and industry, experience in this kind of relationship and areas of interest are factors that differentiate the establishment of motivation. Whereas the motivations for participation in UIC are different for universities and industries (Ankrah & AL-Tabbaa, 2015), understanding the real meaning of each motivation is one of the important drivers for the success of the relationship. (Guimón, 2013) complements stating that successful UIC needs to support the missions and motivations of each partner.

Regarding the motivation for universities collaborating with industries, the literature presents different aspects that may encourage universities to seek collaboration with industries. Based on the knowledge transfer between university and external actors known as third mission of universities, the most important one is the creation, transfer and sharing of knowledge. However, beyond the

third mission, the universities look for ways to improve the training of its students, offering job opportunities to these students and to have access to expertise that they do not have and also to benefit from direct experience in companies (Ankrah & AL-Tabbaa, 2015; Lee, 2000). D'Este and Perkmann (2011) and Muscio and Vallanti (2014) also claim that, in recent years, due to cuts in government funding for research, universities have been more involved with industries, especially to get support for their research activities.

Arza (2010) summarizes and classifies the motivations of universities to collaborate with industries in two types: (i) intellectuals, regarding the exchange of information, education, ideas for new research, new publications and the consequent increase of academic productivity; and (ii) economics, relating to the funding of research.

Regarding the motivation for industries collaborating with universities, the available literature, although wide, is rather directed to developed countries. Probably, because in these countries the UIC has greater experience.

Lee (2000) lists a set of industries' motivations that appear frequently in the literature and support that the motivations for which the industries seek collaboration with university are many and complex, as industries have their own agendas for which they are willing to commit corporate resources.

Systematic review by Ankrah and AL-Tabbaa (2015) shows motivations categorized according to Oliver's six critical determinants: necessity, reciprocity, efficiency, stability legitimacy and asymmetry.

Arza (2010) classifies the motivations of industries to interact with universities in two types: (i) passive, using the results of the interaction for increased operational efficiency; and, (ii) proactive, exploiting the resources and expertise available in universities to develop innovative activities in industries.

Channels of Interaction

Given that the UIC can promote gains for both parties involved in the relationship, it must go through an interface or tangible communication processes (Feng, Zhang, Du, & Wang, 2015). The channels are the systems of interaction existent between the partners that allows the establishment of a relationship.

The authors in the subject consider a variety of channels of interaction may be set up (Nilsson et al., 2010; Sherwood et al., 2011), sometimes they occur simultaneously and in other cases one mechanism is dependent on another, and the emphasis in some channels depends on the motivation of each actor (Franco & Haase, 2015). Dutrénit and Arza (2010) and Arza (2010) add that some channels of interaction are more effective than others in order to achieve certain kinds of benefits. Despite the channel of interaction playing an important role of addressing motivation, it is often possible to observe that, regardless of the motivation, the well-known channels are the first to be addressed (Barnes, Pashby, & Gibbons, 2002).

With regard to literature about channel of interaction, some studies focus on industry (Cohen et al., 2002; Freitas et al., 2013; Grimpe & Hussinger, 2008); other focus on university and industry perspectives (Ankrah & AL-Tabbaa, 2015; Arza, 2010; Bekkers & Freitas, 2008; De Fuentes & Dutrénit, 2012; Dutrénit & Arza, 2010; Polt et al., 2001) and the majority of UIC surveys are concentrated in universities.

Regarding the channel, an important point to emphasize is that university has been treated as a single unit (Bruneel et al., 2010) when in fact it is a complex organization. The report Global Connect (2007) conceptualizes it very well when affirms that university is a permeable system with multiple points of UIC. In other words, there are many doors to the university through which university partners can enter through to develop collaborative relationships. Although the relevance of the subject, most of the studies present in the literature are conducted in the perspective of the individual researcher.

Regarding to types of channels, there are multiple channels that can be used during the UIC. In this work, six groups to classify the interaction channels are identified: (i) information—including publications, conferences, informal contacts, others; (ii) R&D projects—including contract R&D, consulting, and joint R&D; (iii) licenses and patents; (iv) business—including joint or cooperative ventures, purchase of prototypes developed at science, creation of physical facilities, university spin-offs; (v) training—including supervision of PhDs and Masters theses, training of employees of enterprises, students working as trainees; and, (vi) human resources—including personnel mobility, hiring of recent graduates. Table 2 presents compilation of the channels, based on the classification described above, that are cited in the reviewed articles that address this driver. It is also presented the information of which the actors are involved in the studies (U – University and/or I - Industry).

Outcomes of Interaction

According to Ankrah and AL-Tabbaa (2015), UIC is based on the assumptions that the benefits are greater than the (social) cost or risks associated with interaction. The capacity to generate significant outcomes, some expected and others unexpected (Lee, 2000), to the partners and society (Franco & Haase, 2015), has been one of the main factors that has contributed to the expansion of the use of UIC. The literature presents relevant research on this topic.

Regarding the main outcomes promoted by the interaction, they differ between the partners of the relationship, and are strongly associated with initial motivation for interaction and with interaction channel used for this purpose (Arza, 2010). The recent systematic review by Ankrah

and AL-Tabbaa (2015) identifies an extensive list of UIC outcomes realized by universities and industries.

According to Lee (2000), the most significant outcome gathered by industries is an increased access to new university research and discoveries, and the most significant outcome by universities members is complementing their own academic research by securing funds for graduate students and lab equipment, and by seeking insights into their own research.

However, these considerable potential benefits are often not recognized in practice (Barnes et al., 2002; Dooley & Kirk, 2007). The major reason is that collaborations between partners with different models of organization and different culture need considerable management effort in order to be successful.

Table 3. Threats and opportunities to university across different studies

Threats	Opportunities
Greater involvement with industry can corrupt academic research and teaching (De Fuentes & Dutrénit, 2012)	Close collaboration facilitates interactive learning which in turn indirectly benefits scientific production by generating new ideas and motivating new research projects (Arza, 2010; Perkmann & Walsh, 2009)
Shift from basic research towards more applied topics and less academic freedom (P. D'Este & Patel, 2007; Perkmann & Walsh, 2009)	Applied projects offer more learning opportunities during via highly interdependent interaction with industry (Perkmann & Walsh, 2009)
Can reduce the openness of communications among academic research and put restriction on publishing (De Fuentes & Dutrénit, 2012)	Collaborative engagement may benefit academic's research activities by establishing relationships with knowledge users (Pablo D'Este & Perkmann, 2011)
The knowledge becoming obsolete because of withholding the publishing of their results until patenting has taken place (Ankrah et al., 2013)	Researches learn to identify the most valuable research from the pool of their inventions and, therefore, become better at raising private funds (Arza, 2010)
Risks that UICs pose to the integrity of academic investigation, which could undermine public faith in universities and research involving UICs (Ankrah et al., 2013)	

For the UIC to be successful and reach mutual benefits, it is important that the channels are correctly identified in each level of the UIC (Ankrah & AL-Tabbaa, 2015), and having a clear definition of the desired and expected goals by the partners (Barnes et al., 2002). Lee (2000) complements this reasoning, suggesting that the sustainability of the relationship is assigned to a mutual benefit.

Outcomes for Universities

Several authors categorize universities benefits in two relevant outcomes: the intellectual outcomes and the economic outcomes (Arza, 2010; De Fuentes & Dutrénit, 2012; Dutrénit & Arza, 2010). In a recent survey made by Ankrah et al. (2013), social aspect is also focused and is classified in the lowest level, both for universities and industries. At the academy, the most cited social benefit is "interesting and provides personal satisfaction".

The literature point out acquisition of funds for research and lab equipment, and creation of business opportunities as main economics outcomes for universities (Ankrah & AL-Tabbaa, 2015; Ankrah et al., 2013; De Fuentes & Dutrénit, 2012; Lee, 2000). It is also possible to add the opportunity of sharing of equipment and instruments as

another economic benefit (Ankrah & AL-Tabbaa, 2015; De Fuentes & Dutrénit, 2012).

As intellectual outcomes, authors refer gain of insights for further research and collaborative projects, knowledge sharing and opportunity to expose students and university to practical problems and to state-of-the-art technology (Ankrah et al., 2013; De Fuentes & Dutrénit, 2012; Lee, 2000).

It is important to point out that some authors present arguments that the UIC relationship is beneficial and advantageous to universities and there are those who consider harmful and threatening (Perkmann & Walsh, 2009). In the literature examined for this chapter it is possible to observe the conflict between the statements of different authors (Table 3).

Outcomes for Industries

Industry's partnership with universities may result in benefits to the industry to ensure competitive advantage and productivity gains with impact on financial performance (Ankrah et al., 2013; Pertuzé et al., 2010).

According to Ankrah et al. (2013), these collaborations give industries access to diverse resources, sometimes at prices lower than market rates, thus

enabling industry to reduce their overall costs, especially those relating to knowledge creation such as research and development. Another important point is that technological knowledge produced in the universities is the result of a dynamic development based on discussion of previous research results, including detailed documentation of trial-and-error events, which is sometimes difficult for industry to develop internally (Barnes et al., 2002; Grimpe & Hussinger, 2008).

In general, these studies categorize outcomes for industries as: (i) research and development (R&D) – acquisition of complementary or substitute R&D, innovation and new patents and processes; (ii) non R&D – technology transfer, acquisition of solution to solve production problem, acquisition of knowledge and access to qualify human resources; and (iii) quality – quality control and test of products and processes (Arza, 2010; De Fuentes & Dutrénit, 2012; Lee, 2000).

As shown above, social benefits are also classified at the lowest level by industry, being “enhanced image and reputation/credibility with the industrial community” the most cited benefit (Ankrah et al., 2013).

The UIC is based on the assumption that the benefits are greater than the costs and

risks associated with the investment required (Ankrah & AL-Tabbaa, 2015). However, in general, greater investment in resources is done by industry. Then, from the company’s perspective, is expected tangible benefits that include an appropriate return on investment through the value created from the technology generated (Philbin, 2008). However, in the literature reviewed for this chapter, it is possible to identify risks that offer some threat to the industry such as: (i) fundamental differences in the relative priorities, perspectives and time horizons of university and industry (Barnes et al., 2002); (ii), gap between the knowledge produced by university researchers and what is used in practice (Arza, 2010; Franco & Haase, 2015); (iii) the loss of control of vital technology and information leakage about the firm’s new technologies (Ankrah et al., 2013); (iv) other risks cited, like as financial and market risks, risk of incompetent academics in the technology transfer process, risk of incomplete transfer, and risk of non-performance of the technology (Ankrah et al., 2013).

The Figure 2, based on the literature reviewed, presents a resume of the three drivers discussed above.

Figure 2. Motivations, channels of interaction, outcomes of UIC

FUTURE RESEARCH DIRECTIONS

Some directions of future research in this topic could be associated with the need to understand better the UIC relationship. At first, the authors consider that although the UIC be a relationship between two organizations with fundamental differences, it is possible to identify in the literature that the major part of studies emphasizes the impact of the university in the industry. Probably caused by the fact that the authors of research articles working in universities. As an example, is mentioned the article (Cohen et al., 2002), reference too many other articles, which does not refer any impact of industry on university (Feng et al., 2015). It is expected that future researches are needed to examine the contributions and impacts of the relationship in each of the partners. Secondly, despite of universities are complex organizations with diversity and conflicts, many studies in UIC have treated the university as a single unit (Brueneel et al., 2010) and mostly into the individual researcher. Such differences are considered as

major obstacle to successful UIC (Barnes et al., 2002). The development of a systematic procedure of governance and management of UIC relationship is essential to its success.

Finally, it is possible identify others areas for further research: (i) development of a performance measurement system for UIC and, (ii) the shift in modern economies from manufacturing to services sector become this sector an important area for future researches.

CONCLUSION

The aim of this chapter was to approach and understand the three main drivers of the UIC relationship – motivation, channel of interaction and outcome – that the authors consider that may lead this relationship to success and achieve mutual benefits and therefore promote the establishment of a long-term relationship. In order to achieve this goal, the literature was revised and consequently the main motivations to promote

Figure 3. UIC framework

the interactions, the different channels of interaction and the expected outcomes were identified. During the review, it was possible to perceive the key role of the channels for the relationship. The proper identification and definition of channels of interaction allow the motivations are properly addressed and consequently the outcome achieved. Even if the motivation is very well outlined, the incorrect identification of the channels will lead to failure in achieving the goals and the failure of the relationship, undermining future actions of partnership. The authors also recognize, considering the differences of culture and organizational models between the partners involved in the UIC, that it is critical for the success of this relationship the establishment of a governance model for relations of partnership between universities and industries. The industry has the opportunity to support this aspect for its large experience in developing and implementing projects. The figure 3 presents a framework to the understanding of the UIC relationship, based on the three main drivers described above.

ACKNOWLEDGMENT

The authors would like to thank the editor and the anonymous reviewers for their constructive comments and suggestions which contributed to the enhancement of this chapter.

In a general manner, the relevant suggestions and comments have been incorporated in this reviewed version.

KEY TERMS AND DEFINITIONS

Channel of Interaction: Mechanisms of interaction existent between the partners of a relationship.

Governance: The establishment of policies, and continuous monitoring of their proper implementation to ensuring effectiveness.

Informal Collaboration: Mechanism that does not involve any contractual relationship between the university and the industry.

Motivation: Internal and external factors that stimulate to attain a goal.

Outcome: Consequence or conclusion after a period of time, which can be one result, multiple results, or no results.

Types of UIC: Organization forms of UIC relationship.

University-Industry Collaboration (UIC): Bi-directional relationship between university and industry entities, established to enable the diffusion of creativity, ideas, skills and people with the aim of creating mutual value over time.

Using Communities of Inquiry Online to Perform Tasks of Higher Order Learning

INTRODUCTION

Given the growth of online collaborative learning in higher education and the proliferation of technologies that facilitate it, it is critical to gain a better understanding of the mechanisms that promote quality. In this sense, the community of inquiry (CoI) model (Garrison, Anderson, & Archer, 2000) represents one of those mechanisms. This model is useful to describe the development of online collaborative learning, taking into account the processes of instructional dialogue that can facilitate successful online learning (e.g., Akyol & Garrison, 2011; Szeto, 2015). The CoI model explains the online learning as a by-product of collaborative work between active participants in a learning community characterized by proper orchestration between three components: the online pedagogical environment (teaching presence); social/referee support (social presence); and the cyclical process of interaction that allows meaningful learning within the student community (cognitive presence).

The overall objective of the study presented in this article is to use the CoI model to deepen understanding of the mechanisms that facilitate successful online learning when students tackle learning tasks of a higher order. There is evidence

showing that the nature of the learning task modulates the profile of the learning process; however, we consider that there is insufficient evidence to obtain patterns to monitor group relations in similar contexts.

For this purpose, authors have combined two techniques of analysis: quantitative content analysis (QCA); and social network analysis (SNA). QCA is a process involving searching text according to a defined scheme, and is used to identify frequencies. The CoI model provides the category system used in this study.

The authors have also used SNA because of its ability to explain the nature of group relations, based on the flow of information and communication found in the interactions of participants. SNA has been used by several researchers to improve understandings of individual and group online learning dimensions. However, few of these studies have used a comprehensive conceptual framework that considers the core elements of the CoI model.

Therefore, with the support of QCA and SNA, and using as the conceptual framework of the CoI model, the specific objectives of this study is to determine the influence of group social structure and centrality of coordinators on social and cognitive activity for the different types of collaborative learning task.

BACKGROUND

To achieve the stated objective, this section describes the conceptual frameworks and the background used in this empirical study.

Community of Inquiry (CoI) Framework

During the last fifteen years, many researchers have both studied and analyzed educational experiences according to the CoI model (e.g., Akyol & Garrison, 2011; Szeto, 2015; Author). The CoI model focuses on learning processes from a collaborative constructivist point of view. The model also assumes that learning in online environments occurs through the interaction of three core elements: social presence, cognitive presence, and teaching presence. These elements work together to support deep and meaningful online inquiry and learning.

The first element, social presence, is defined as the ability of learners to project themselves socially and affectively into a community of inquiry (Rourke, Anderson, Garrison, & Archer, 1999). Social presence is divided into three categories of affective, interactive, and cohesive presence, which reflect a supportive context for emotional expression, open communication and group cohesion for task resolution respectively. Social presence, a factor critical to face-to-face teaching, is challenging to facilitate in online learning environments.

However, social presence is essential to collaborative learning experience and is an essential element in establishing cognitive presence. Cognitive presence refers to the extent to which online learners can construct and validate meanings based on communication and thinking (Garrison et al., 2000, 2001).

The CoI model categorizes cognitive presence into four phases: a triggering event (an issue is identified for inquiry); exploration (exploring the issue through discussion and critical reflection); integration (constructing meaning from the ideas

developed through exploration); and resolution (applying new knowledge into a real world context), with specific descriptors for each phase.

The third element of the CoI model is teaching presence. It consists of two general functions: (1) the design of the educational experience; and (2) facilitation among the teacher and the students. It is the responsibility of the teacher to design and integrate both cognitive and social presence for educational purposes through scaffolding, modeling, and/or coaching.

Interest in understanding the processes of learning through the CoI framework, and its relationship with learning outcomes of higher order is based on the study by Marton and Saljo (1976), in studying different learning strategies used by students and their different results. Marton (1988) indicated that lesson learned, and how it is learned are two inseparable aspects of learning. Therefore, the process and the result are intimately associated. In this sense, Akyol and Garrison (2008) conducted a study through content analysis, in order to show how the CoI framework progresses during the learning process, finding that cognitive and teaching presence are determined primarily by the task and not by time.

The results from research on the CoI framework, have shown the importance of considering the disciplines, and contents/coursework as study variables. However, there are few studies which deepen the processes and outcomes (related) learning

Social Network Analysis

In general, a social network can be defined as a group of entities that collaborate or compete. Mathematically, this is a graph, in which each participant is represented by a node. The relationships between nodes are represented as links between the corresponding nodes.

Social network analysis (SNA) provides useful information and quantitative indicators of the quality of the learning process as a way to effectively analyze the process of co-construction of

knowledge in a CoI (e.g., Shea, Hayes, Uzuner et al., 2013). It also allows for description, analysis and visualization of the patterns of interaction and social structures of the online groups formed by students, offering a multitude of network indicators to evaluate the process and quality of the knowledge construction of students from a social perspective (Nistor et al., 2014).

In this study, the authors will focus on some of the variables most used in SNA, for both individuals and groups: centrality degree, centralization, and cohesion.

Centrality degree is the measure of the interaction considering the directionality of the sending or receiving of messages. The idea is that if a subject is central in their group then they will be the most popular and get the most attention. Centrality is an important measure because previous research has found that it correlates with positive learning outcomes. Centrality can be of two types: centrality in-degree (in) and centrality out-degree (out). Centrality (in) is indicator of network prestige, and centrality (out) is indicator of influence. Prestige measures the number of incoming responses directed to a student's discussion post, and represents the degree to which other students seek out that student for interaction (deLaat, et al., 2007). Students with high prestige are notable because their opinions may be considered more important than others in the network. Students with high influence are in contact with many other students because they initiate a large number of discussion posts to others (see Shea et al., 2013). Some authors found that participants who occupy central positions in the formal network are more likely to put forward ideas and suggestions on teamwork.

Network centralization refers to the extent to which a structure of relationships is centered on a student. Centralization of the network can be of two types: centralization in-degree (in) and centralization out-degree (out). Centralization (in) refers to the extent to which a group is focused on a subject, that is, who most group members directed their interventions towards. Centralization (out) refers to the extent to which a group

is focused on a subject, that is, who among the group engages in most of the interventions. A positive relationship has been identified between cohesion and centralization (in) of the forum and these associations' direct effects on knowledge construction in communities of inquiry (e.g., Tirado, Hernando & Aguaded, 2012). However, the centralization (out) has also shown to be inversely related (Thormann, Gable, Fidalgo & Blakeslee, 2013), to categories (Newman, Webb, & Cochrane, 1995) of critical thinking.

Cohesion describes the general level of linkage among the actors in the network (Scott, 2000). Cohesion is the forces holding the individuals within their groupings (Yang & Tang, 2003). In some cases, high levels of cohesion and centralization of the group can be good predictors of teamwork, achievement of the results of the learning task (Yang & Tang, 2003), and critical thinking phases of Gunawardena and colleagues' model (Aviv, Erlich, Ravid & Geva, 2003).

However, these advances show the overall performance of the model. Although the task (outcome) learning is generally considered in most of these studies are still few studies that integrate the type of learning task analysis among the variables.

Therefore, given the relevance of the learning task in defining the learning process, it is necessary to conduct studies that consider it as a central element in the analysis of model performance.

Bloom's Taxonomy

The current study focuses on required tasks in an online— and self-regulated—learning environment. Specifically, the authors wondered if the type of academic task proposed in a CoI would determine the frequency of the social and cognitive actions of a group of online learners. Bloom's taxonomy, a well-known and widely used schema, was used to better understand the systematic classifications and processes of thinking and learning in an online learning environment. In the current study, the authors considered three higher order

thinking levels from the revised Bloom's taxonomy (Anderson & Krathwohl, 2001, pp. 67–68): (a) *Analyzing* (breaking material into constituent parts and determining how the parts relate to one another and to an overall structure or purpose by differentiating, organizing, and attributing); (b) *Evaluating* (making judgments based on criteria and standards by checking and critiquing); and (c) *Creating* (putting elements together to form a coherent or functional whole, and reorganizing elements into a new pattern or structure by generating, planning, or producing).

The research question is: Using SNA metrics and QCA, how does social structure influence the level of group social and cognitive presence in each type of learning task? In addition, how does the level of intervention [centrality (out)] and popularity [centrality (in)] of the coordinators influence the social and cognitive presence of the group?

METHOD

During three academic years (2010-11, 2011-12 and 2012-13), a total of 206 university students from different degree areas and from 9 universities across Andalusia, Spain participated in the current study. Each of these students participated in a common online course. The first year, 71 students participated in the course; the second year, 77 participated; and, the last year, 64 participated.

Experimental Setting

The present study took place at the Virtual Campus of Andalusia, Spain where students from 9 public universities from the Andalusian region of Spain participated in a common online course through Moodle LMS. The online course is called, "Intervention on risk behaviors". This course is offered since 2008 to the present. It can enroll up to 10 students from each of the public universities of Andalusia, and from different academic areas (social, engineering, experimental, and health). The study was based on group discussions among the participating students. A total of 96 discussion forums were conducted: 8 groups per three academic years for each of four group activities (including the first socialization activity which was not included in the analysis).

Moodle discussion forums were employed to facilitate content delivery and to promote higher order thinking skills among the students. The required tasks were based on the skills that are present in the top three categories of the revision of Bloom's taxonomy. The course design was inspired by the model of Salmon (2013), because provides a staged, practical approach to teaching and learning online. In accordance with this model, was following steps:

In Step 1, 8 working groups were established, each one into a discussion forum where students were given directions for how to proceed by the tutor. In step 2, the first actions were performed, in order for students to socialize, exchange mes-

*Based on Bloom's taxonomy

sages, interact and learn. In the step 3, three types of tasks were presented (Table 1) with different levels of cognitive demand that required participants in each group to share information, begin to engage in group work, and to share the same learning goal. In step 4, the learners focused on knowledge development and discussion activities.

To conduct the assigned tasks, each of the eight working groups were provided a private forum to work together, and a file space for uploading or downloading documents. They were offered theoretical and practical resources that also served as reference material and support for the implementation of the tasks. Two different moderators were selected by each group to coordinate each task. One instructor monitored the interactions, becoming active only in case of necessity.

Measures and Procedures

Data were collected using the messages in the forums created by each group, using the instruments developed by Anderson et al. (2001), Garrison et al. (2000, 2001) and Rourke, Anderson, Garrison, and Archer (1999) as references for measuring social presence and cognitive presence. For the QCA, the units of analysis were the *units of meaning*, not the specific messages (Rourke et al., 2001). Depending on the semantic sense used, several units of meaning could be conveyed in each message. A total of 13,501 units of meaning were coded into the qualitative analysis program AtlasTi v.6. Finally, data was imported to SPSS v.21 in order to perform quantitative analysis.

In accordance with the principles of systematicness, objectiveness, and reliability of QCA indicated by Rourke and Anderson (2002), three coders classified the messages using the CoI model (Appendix 1 and 2). The researchers followed the categorization of the CoI model and coded the messages into cognitive or social presence, including indicator notes for each message. The statistical package macro (KALPHA) by Hayes & Krippendorff (2007) was used for the calculation of the interrater and intra-rater reliability coef-

ficient Krippendorff's alpha. The global output from the macro Krippendorff's ordinal α is 0.766, a modest degree of interrater reliability. The data was then imported into SPSS v.21 in order to conduct quantitative analysis. In the numerical matrix of imported data, each indicator becomes a quantitative variable that reflects its frequency for each participant.

In order to perform the SNA, the authors considered individual and group variables associated with the structure of the groups (Appendix 3). The authors identified the network properties as density, cohesion and centralization index and used them to explain the structure of interpersonal communication. The data were entered into UCINET 6 for Windows (Borgatti, Everett, & Freeman, 2002), where rates of the different variables were obtained for SNA. Finally, data was imported to SPSS v.21 in order to conduct quantitative analysis.

The statistical analysis of data was performed using measurements of QCA and SNA. The linear regression analysis was used. With this analysis the influence on social and cognitive presence of the social structure of the group (density and centralization [out/in]) and the level of intervention/popularity (centrality [out/in]) of group coordinators was identified.

RESULTS

Based on the analysis of linear regressions, the following results were obtained (Table 2).

The results regarding the influence of the group structure on the social and cognitive presence of the group were as follows:

1. The density of the group directly influenced all categories of social presence and cognitive presence in the three learning tasks; however, the strength of this influence depended on the type of learning task. In this sense, density had more influence in the categories of social presence than in

* $p < .05$, ** $p < .01$, *** $p < .001$

the categories of cognitive presence in the ACS task. Instead, density more strongly influenced exploration, both in the EW task ($\beta[\text{Exp}] = .57$, $p < .001$), and the CWQ task ($\beta[\text{Exp}] = .66$, $p < .001$).

- Moreover, centralization (out) usually inversely influenced all categories of social and cognitive presence, with a more negative influence on the ACS task than on the rest of the learning tasks.

3. However, the influence of centralization (in) on the categories of social and cognitive presence was usually variable, depending on the type of learning task. Its influence on the categories of social presence was direct and significant in the ACS and EW tasks, but it was not significant in the CWQ task. Also, in the EW task, its influence was also significant in the activation ($\beta[\text{Act}]=.27$, $p<.001$) and exploration ($\beta[\text{Exp}]=.16$, $p<.01$) categories. However, while there was a direct effect of centralization (in) on the activation category of the CWQ task ($\beta[\text{Act}]=.40$, $p<.001$), its effect on the same category was reversed in the ACS task ($\beta[\text{Act}]=-.42$, $p<.001$).

The results regarding the influence of the coordinators on the social and cognitive presence of the group are as follows:

1. The centrality (out) of coordinators often had a direct influence on the three types of task, although the nature of the learning task modulated its effect on the social and cognitive presence categories.
2. In ACS, the influence of the centrality (out) of coordinators was positive and significant in almost all categories of social presence ($\beta[\text{Aff}]=.63$, $p<.001$; $\beta[\text{Int}]=.46$, $p<.05$; $\beta[\text{Exp}]=.47$, $p<.05$) and cognitive presence ($\beta[\text{Act}]=.75$, $p<.001$; $\beta[\text{Exp}]=.59$, $p<.01$; $\beta[\text{Inte}]=.46$, $p<.01$).
3. However, in the EW task, there was a positive and significant influence on the social presence categories of affective and interaction ($\beta[\text{Aff}]=.70$, $p<.001$; $\beta[\text{Int}]=.56$, $p<.01$) and on the cognitive category of activation ($\beta[\text{Act}]=.57$, $p<.01$).
4. Moreover, in the CWQ task, the influence was positive and significant on the interaction and cohesion categories of social presence ($\beta[\text{Int}]=.69$, $p<.001$; $\beta[\text{Coh}]=.35$, $p<.05$) and on the cognitive category of exploration ($\beta[\text{Exp}]=.77$, $p<.001$).

5. A significant influence regarding the centrality (in) (prestige) of coordinators was not seen in any of the three learning tasks.

DISCUSSION AND EDUCATIONAL IMPLICATIONS

In a CoI in which the learning task is ACS, the factor that facilitates social presence in the group is a dense social presence and a small centralized network. Moreover, the coordinator occupies a prominent role, triggering the problem definition, the exchange, and integration of ideas, and the proposed solutions; however, it is especially necessary for other members of the group to be active in suggesting ideas and providing data relevant to the resolution of the case.

In a CoI in which the learning task is EW, the search for consensus and the definition of evaluation criteria is a precondition and the fundamental condition to be solved. This first concern is usually led by the group coordinators with the involvement of other group members. In this case, the forum was a whole communication space with a very important consultation and resolution role, allowing coordinators and other group members to address problems.

In a CoI in which the learning task is CWQ—the less structured task—the density of group interactions is a very important factor, as is the actions of coordinators in searching for consensus and the exchange of proposals and suggestions. The prestige of the coordinators is also important so that group members will consult them.

FUTURE RESEARCH DIRECTIONS

One limitation of this case study is that it focused on three learning tasks that attempt to represent the top three levels of Bloom's taxonomy (analysis, evaluation and creation). Given that it is difficult to find practical examples suitable for Higher Education, which represent the exact taxonomic levels,

in later studies it will be appropriate to specify learning objectives in each of the task areas and to conduct more modular analysis.

Considering that cognitive presence includes self-reflection and co-construction of knowledge, for a better understanding of cognitive activity in a community of inquiry it would seem appropriate to incorporate an analysis of meta-cognition (e.g., Bjork, Dunlosk, & Kornell, 2013) especially in online self-regulated learning environments (e.g., Garrison & Akyol, 2013; Kovanović et al., 2015).

CONCLUSION

Understanding the mechanisms that favor successful online learning experiences in higher education remains a prime target. Although many pedagogical models designed to exploit the virtues of technology in higher education have been developed, they provide insufficient empirical evidence to guide educators and students in developing online learning processes.

In this study, using methods such as QCA and SNA, it has been found that the nature of the learning task determines the social structure of the group (cohesion and centralization) as well as the centrality of the coordinators on the social and cognitive actions of students.

KEY TERMS AND DEFINITIONS

Centrality: The measure of the interaction considering the directionality of the sending or receiving of messages.

Cognitive Presence: Refers to the extent to which online learners can construct and validate meanings based on communication and thinking.

Cohesion: Describes the general level of linkage among the actors in the network.

Network Centralization: Refers to the extent to which a network is centered on a subject.

Social Presence: The ability of learners to project themselves socially and affectively into a community of inquiry.

Teaching Presence: The design of the educational experience and facilitation among the teacher and the students.

Category	Indicator	Examples
Affective	Expressions of emotions	"This is a little confusing at first..." (JAL_T1_GC_2013)
	Use of humor	"Put a picture in your profile for people to know how cute you are:D" (IRP_T1_GH_2012)
	Self-disclosure	"I have had personal problems" (FMA_T1_GE_2012)
	Apology	"I am sorry, I am late =S" (SPA_T1_GA_2012)
Interactive	Referring explicitly to others' messages	"As our colleague said ..." (PC_T3_GB_2012)
	Asking questions	"How can we know who are the members of our group?" (CME_T1_GC_2012)
	Expressing appreciation	"Thank you very much for the link" (JPT_T3_GA_2013)
	Expressing agreement	"Your thoughts seems very good, I agree with you" (MPF_T3_GG_2013)
	Expressing disagreement	"I understand your position, but I do not agree" (PZV_T3_GC_2013)
	Inviting, suggesting	"What you think if tomorrow we send the activity ..." (BLM_T2_GD_2012)
Cohesive	(Vocatives) Addressing peers by name	"Thanks Ana for offering" (FMA_T1_GF_2012)
	Addressing the group as we, us, our, group	"We have done an excellent job" (TCF_T3_GC_2012)
	Communicating solely for social function	"I'm glad you're feeling better" (MVM_T3_GH_2013)

APPENDIX 2

Table 4. Cognitive presence coding scheme

Category	Indicator	Examples
Triggering	Recognizing the problem	"We must follow some certain guidelines to do the task" (PRM_T3_GC_2013)
Exploration	Divergence of ideas	"We need to reach an agreement" (IRP_T1_GH_2012)
	Exchanging ideas	"Ask about their responsibility, as a result of the problems at school" (LAT_T1_GE_2013)
	Suggestions for consideration	"I'm sharing a very good link, when I saw this video I thought about the issue that concerns us right now" (JMH_T1_GF_2013)
Integration	Convergence among group members	"Just as my colleague, I totally agree that there are thousands of cases" (MDE_T1_GG_2012)
	Connecting ideas, inference, synthesis	"In summary, we have the following tasks..." (VDC_T3_GH_2013)
	Creating solutions	"For example, a possible solution would be to propose extra-curricular activities" (ZMJ_T1_GD_2012)
Resolution	Application to real world	"It is a good idea for people to become aware of what they really know or think they know" (FSY_T2_GB_2012)

APPENDIX 3

Table 5. Metrics for social network analysis

Factor	Measures
Degree Centrality (out/in)	Is the number of incoming and outgoing ties, and indicates how well an actor is connected within the overall network. Valued by: • Centrality (out) is the number of messages sent by the student. • Centrality (in) is the number of responses to messages sent by the student.
Centralization (out/in)	Its measurement is comprised of an overall value between 0-100. A star network (approximately 100 value), for example, would indicate that there was a central subject that everyone was linked to without any other connections among them. Therefore, it is assumed that all communication is channeled by a central actor. On the other hand, a fully connected network (approximately 0 value) means there are no central actors, but all communication is distributed to all members of the group (all linked actors).
Cohesion	The cohesion is measured by the density index (Berkowitz (1982). $Density = 2a / n(n-1)$, where a = the real number of interactions and n = the number of participants in the network. It is calculated by dividing the number of real relationships between the number of possible relationships and multiplying by 100.

INTRODUCTION

One of the major issues in modern computer architecture is multicore design. Programmers have been urged to design innovative algorithms by exploiting multicore facilities. Synchronization, i.e., the technique adopted for coordinating threads or processes to have appropriate execution order, is one of the main issues in programming on a multicore processor. In the literature, many synchronization techniques based on hardware and software have been proposed (Petrović, 2014; Yoo, 2013; McKenney, 1998). Modern computers provide special hardware instructions that allow to test and modify the content of a word atomically (e.g., the *cmpxchg* instruction of Intel) which can be used for synchronization of threads (Valois, 1995; Gao, 2007). Software techniques can synchronize threads without any dependency on hardware instructions (McKenney, 1998; Mellor-Crummey, 1991). One important aspect of a synchronization algorithm is its performance, which is evaluated in terms of overhead. In this study, the term cost is used to address an overhead of synchronization algorithm. The state-of-the-art approaches strive to increase the performance by

reducing the cost of the synchronization. To the best of the authors knowledge a study to analyze the possible costs of synchronization mechanisms is absent. So, this chapter investigates the costs in the main steps of a synchronization mechanism. Moreover, since memory access is one of the most important costs in synchronization mechanisms, a discrete time Markov chain model of memory access cost is presented to evaluate the memory access overhead.

The remainder of this chapter is organized as follows. The primitives of the main synchronization algorithms are described in Section 2. Then, a theoretical evaluation of each cost and experimental results are presented in Section 3. Finally, some conclusions are described in Section 4.

BACKGROUND

When threads are working simultaneously on a shared object, their synchronization should be managed properly, otherwise the instructions of different threads interleave on the shared object in a wrong way. For example, Figure 1 shows the program order of two threads that are working on

DOI: 10.4018/978-1-5225-2255-3.ch346

Figure 1. Incorrect execution of the instructions order

the shared object counter (Silberschatz, 2006). Since one thread is incrementing the counter and another one is decrementing it, at the end, the counter is expected to have the initial value. However, as Figure 1 illustrates, there is a possible execution order of instructions that leads to an incorrect result.

Synchronization mechanisms are used to avoid the problematic interleaving instructions. The part of the code that accesses to the shared object is called critical section. The critical section should be protected by synchronization primitives to avoid concurrent access to the shared object:

- Ticket lock is a synchronization mechanism to guarantee fairness execution to all the threads. Ticket lock is a kind of spin-lock that keeps checking to see if a lock is available to acquire the lock. Ticket locks are conceptually two bytes, one indicating the current head of the queue, and the other one indicating the current tail. The lock is acquired by atomically noting the tail and incrementing it by one (thus adding it to the queue and noting the position), then

waiting until the head becomes equal to the initial value of the tail (Piggin, 2008).

- Filter lock is a synchronization algorithm that works for multiple threads. The filter lock creates $N - 1$ waiting lists, called levels. A thread must pass through all the levels before entering the critical section. As shown in Figure 2, at level 0 at most N threads are waiting. In level 1, at most $N - 1$ threads are waiting. The procedure continues till level $N - 1$, that corresponds to the critical section, in which only one thread is enabled to enter. Each level should satisfy two properties: first, among the threads that are trying to enter into a level, at least one thread succeeds. Second, at least one thread is blocked in the level (Herlihy, 2006).
- Readers -writer lock (rwlock) is intended a solution for solving the readers-writers problem, where a resource is shared among readers and writers. The readers-writers problem happens when a reader starts to read the first item of the shared resource, then stores it in a local variable.

Figure 2. Filter lock structure

Subsequently, a writer updates the shared resource. Afterwards, the same reader reads the second item of the shared resource. Obviously, in this case the reader reads inconsistent data. Rwlock is a solution for solving this problem through postponing a writer till all the readers complete their operations.

- Read-Copy Update (RCU) significantly reduces the overhead in Readers-writer lock (Desnoyers, 2012). The key point is to safely read data even when they are being modified by an update. Coherence between readers is kept by maintaining multiple versions of the same data and ensuring that they are not freed up until all pre-existing read-side critical sections are completed. There are two types of RCU: the general-purpose RCU that uses a global variable to synchronize the readers and the writer, and the signal-based RCU that uses Portable Operating System Interface (POSIX) signals from the write side for synchronization.
- Test_and_set instruction atomically stores '1' in a memory address, and returns its old content. This instruction can be used for implementing a synchronization mechanism: the critical section is protected by `__sync_lock_test_and_set()` and `__sync_lock_release()` statements that use test_and_set instruction inside (Herlihy, 2006).

COST OF SYNCHRONIZATION ALGORITHM

In this section, different costs of synchronization procedures are described. Furthermore, experimental results of each cost are presented by exploiting above-mentioned synchronization algorithms on a node of cluster (Opteron 6276 2.3 GHz CPU with 16 cores and running CentOS 6.3 Operating System). Experiments are compiled with gcc 4.4.7. The benchmarks are implemented with empty critical section except the experiments in Section 3.1 that read and write a single shared variable. An empty critical section is selected to eliminate the impact of the critical section on the performance.

MEMORY ACCESS

Moving a synchronization algorithm from a uniprocessor to a multiprocessor environment can improve the performance, but the improvement is not proportional to the number of CPUs due to the cost of communication among processes (or threads). The process communication in a uniprocessor environment has a lower cost due to the lower cache misses (memory access) to retrieve the shared object and flags to keep synchronization in the processor. Instead in a multiprocessor environment, objects and locks are shared among

Figure 3. Cache state

different CPUs. So, updating a shared object in a CPU causes the invalidation of the data cache in the other CPUs. So, the number of cache misses has a big influence on the performance of the synchronization algorithm. In this study, memory access cost is the number of cache misses in a synchronization mechanism. Cache misses are strictly related to data locality, which can be temporal or spatial. Spatial locality means that near addresses are accessed in the near future, so, a block of addresses are fetched to the cache. Temporal locality means that recent memory can be reused in the near future, so, it should be kept in cache memory. In general, there are different techniques to improve data locality. For example, data prefetching technique imports probable data earlier than access time to reduce cache misses. Flat combining (Hendler, 2010), asymmetric multicore (Suleman, 2009) and critical section migrating (Lozi, 2012) delegate the critical section execution to a server thread that improves the cache locality. Cache compression technique compresses recent data in the cache to reuse them in the near future (Alameldeen, 2004). Furthermore, a compiler can optimize the code to improve cache locality (Carr, 1994). In multicore architecture, each core has its own cache.

If an object is shared among some cores, the coherence of their caches should be considered. For example, if a data is shared in the cache of two

cores, and one core updates its value, the data on the other cache is not valid anymore. The cache coherence protocol takes care of this problem in modern CPU architectures. If the data of the cache are not valid, the cache coherence protocol should retrieve the fresh copy of the data from the first accessible memory. The operation of retrieving the fresh data has a cost on the performance of the program. Based on the validity of the data in the cache, different classifications of the cache states are proposed in literature (Sorin, 2011). MESI protocol (Papamarcos, 1984) is a standard cache coherence protocol in modern computer architectures. It classifies the state of the cache to Modified, Exclusive, Shared and Invalid (MESI).

Figure 3 shows the state transition of two caches on different CPUs: each box shows the state of the cache on both CPUs. Initially, an object is shared between two CPUs so the cache states of two CPUs are Shared (S). If a core updates its cache, it modifies its state to Modified (M). By means of a message exchanged with the other caches it notifies other cores that their copies of data are Invalid (I). If a core updates or reads its cache in the Modified state, the state does not change. On the contrary, if it reads its cache in the Invalid state, the state goes back to the Shared state. If a cache with the Invalid state updates its cache, it should retrieve the fresh copy of the data and update it. So, the cache state changes to the Shared state. Also,

the cache that has the copy of the data changes the state to Shared. The thickest lines represent expensive operations in cache coherence protocol.

A model is proposed to evaluate the impact of the expensive operations of the cache coherence protocol. The shared object is written and read by both cores at the same rate (ρ is the update probability and ρ' is the read probability). Since update and read of the shared object are discrete time operations, the state of the cache can be modeled by a Discrete Time Markov Chain (DTMC). Figure 4 shows the proposed DTMC model of the cache states of two cores. Each state of the model shows the cache state in the core: 1 means that the state of the cache for the shared object is valid (Modified, Exclusive, Shared), and 0 means that the cache state is invalid (Invalid). Initially, the state of the cache is valid. If a cache updates the shared object, its status remains 1 but the status of the other cache becomes 0. In both (0, 1) and (1, 0) states, if the core with state 0 reads the shared object, the cache coherent protocol should retrieve the fresh copy of the data and the states become (1,1). Moreover, in both states (0, 1) and (1, 0) it might happen that the core with invalid cache state decides to update the shared object. First, it should read the latest data and update the shared object. As Figure 4 shows, when C1, C2 and C3 states are visited, the cost of the cache coherence protocol should be paid.

The average cost of the model in n operations is computed as following:

$$E[\text{Cost}] = \frac{n}{\mu_{c1}} \times E[C_1] + \frac{n}{\mu_{c2}} \times E[C_2] + \frac{n}{\mu_{c3}} \times E[C_3]$$

where $E[C_1]$, $E[C_2]$ and $E[C_3]$ indicate the average cost of cache coherence protocol in associated states. μ_{ci} indicates the expected required operations to go back to state C_i leaving the C_i state. μ_{ci} is computed as:

Figure 4. Markov model

$$\mu_{ci} = \frac{1}{\pi_{iC_i}}$$

where π_i is the stationary distribution of state C_i . Stationary distribution indicates the measures of the distribution in a long process. After computation of μ_{ci} and in case that $E[C_1] = E[C_2] = E[C_3] = C$, the formula will be:

$$E[\text{Total Cost}] = n \times C \times \left[\frac{(4\rho - 3\rho^2)(1 - \rho)}{2\rho^3(3\rho + 1)} \right]$$

As the formula shows, the cost of the cache coherence protocol in n operations has direct relation with ρ (update probability). So, the final formula can be written as a function of ρ . In the following, the function $f(\rho, n)$ shows the average of the cache coherence protocol cost to retrieve a fresh copy of data in n operations:

Figure 5. Generalized model of cache miss cost

$$f(\rho, n) = n \times C \times \left[\frac{(4\rho - 3\rho^2)(1 - \rho)}{2\rho^3(3\rho + 1)} \right]$$

As described before, there are different techniques to attenuate the number of cache misses. Let assume that $g(n)$ indicates the cost of the cache miss attenuation technique in n operations. The technique is feasible if:

$$g(n) < f(\rho, n)$$

A generalized Markov model is presented in Figure 5. Each state (n, m) represents the number of valid cache states (n) and invalid cache states (m). It is assumed that initially all the states are valid $(n, 0)$, and there are n cores in the system. ρ_n' specifies the probability that n cores read their own caches without writing it. ρ_n specifies that at least one of the n cores tries to update its own cache. Moreover, α_n specifies the probability of accessing the bus among n cores.

To verify the effect of the memory access on the performance of the synchronization mechanisms, some experiments with RCU technique on different rates of update have been performed. The RCU technique was selected because it is a

non-blocking algorithm and it shows more clearly the cost of the memory access effect in critical section. The experiments have been executed with 1 update out of 1,000 and 1,000,000 reads. Figure 6 shows that the performance of RCU with low update rate is higher. As discussed, on high speed update environment there are higher cache misses and consequently higher memory accesses to retrieve the fresh copy of the data, determining a significant impact on the performance.

SPINNING

In a synchronization mechanism, spinning is the act of querying (or in some cases modifying) an object in memory, and waiting for its content. Usually, it is a busy operation that wastes CPU cycles. When the desired content is achieved, the thread can enter into the critical section. This operation is called lock acquiring. High contention for acquiring a lock generates intensive bus traffic. Moreover, the contention for acquiring the lock increases when the thread that acquired the lock spends a significant CPU time in the critical section. Also, it should be considered that the spinning algorithm on uniprocessor architecture is not

Figure 6. RCU with different ratio of update/read

efficient since a thread will completely waste its time slice spinning for a content change that cannot happen until the releasing thread is scheduled. High contention for acquiring the lock generates bus traffic, and should be properly managed. In this study, spinning cost address the waste CPU cycles of threads to enter critical section.

Exponential backoff is a frequently used method for bus traffic attenuation (Herlihy, 2006; Mellor-Crummey, 1991; Anderson, 1990; Petrovic, 2015). It proposes a delay to access memory. One possible implementation of the exponential backoff technique is shown in Figure 7 (Herlihy, 2006), where *MinDelay* represents the minimum delay, *MaxDelay* represents the maximum delay and *Limit* shows the current delay. First, *Limit* is initialized to *MinDelay*. Then, backoff is set to a random number between 0 and *Limit*. If acquiring the lock was unsuccessful, the limit should be doubled and again backoff is set to a random number between 0 and *Limit*. This procedure can be continued until *Limit* becomes lower than *MaxDelay*.

Intel adds *monitor* and *mwait* instructions to improve performance (Boggs, 2004). The *monitor* instruction specifies a range of addresses to monitor events in the memory range. The *mwait*

instruction is used to indicate that the software thread is waiting for an event. A waiting thread can enter an optimized state until the occurrence of desired events. So, it avoids busy waiting and saves power consumption.

Another technique to implement spinning in an efficient way is scheduling another process or thread when a thread is waiting without performing useful operation. The cost of context switch should be considered. For example, if a thread spins for

Figure 7. A possible implementation of the backoff technique

```

Limit= MinDelay;
Backoff= random(0, Limit);
while(1){
    if (!try_acquire_lock()){
        sleep(Backoff);
        if (Double * Limit< MaxDelay)
            Limit=Double * Limit;
        Backoff= random(0, Limit);
    }else
        break;
}

```

few CPU cycles to acquire the lock, scheduling another process is not efficient because the cost of context switch is higher. So, this technique is useful when threads spin for long time.

A non-blocking algorithm can safely access to shared data without the use of traditional synchronization primitives. There are two types of non-blocking thread synchronization algorithms: lock-free and wait-free. In lock-free systems, any thread may be blocked for some time by other threads. Lock-free algorithms increase the overall throughput of a system by occasionally increasing the latency of a transaction. By contrast, wait-free algorithms ensure that no thread can be blocked by another thread. A read operation of RCU is an example of a wait-free system. An experiment with two different synchronization algorithms, i.e., RCU and readers-writer lock, has been performed in order to verify the effect of spinning on the performance of synchronization. Since RCU is a non-blocking algorithm, the performance of RCU is significantly higher than the readers-writer lock, as shown in Figure 8.

SYSTEM CALL AND HARDWARE SUPPORT INSTRUCTIONS

Some synchronization mechanisms require system calls or hardware instructions to acquire a lock, but the performance is penalized because system calls and hardware instructions are heavy operations. On the contrary, user-level locks such as RCU, ticket lock, filter lock, etc. should be used to optimize the performance. Test-and-set synchronization, which uses test-and-set atomic instruction, and ticket lock, which is a user level synchronization algorithm, are compared in order to verify the impact of hardware instructions. As shown in Figure 9, ticket lock outperforms the test-and-set due to lighter instructions.

BARRIER

Barriers are a hardware/software support to correctly implement a synchronization mechanism. They avoid reordering of store and load operations

Figure 8. RCU synchronization method vs rwlock

Figure 9. Ticket lock vs test-and-set lock

in multi-thread programming in parallel environment. In this study, barrier cost is the overhead of the barrier instruction in a synchronization algorithm. A memory consistency model specifies the behavior of multithreaded programs executing with shared memory (Sorin, 2011). There are different consistency models like Sequential Consistency (SC) and Total Store Order (TSO). In a SC model, instructions are not allowed to reorder neither by compiler nor CPU. Instead, in TSO if a Load instruction is followed by a Store instruction in the program order, this order is not guaranteed in execution. So, in TSO model, programmers (or compilers) can prevent the reordering of mentioned instructions through a barrier instruction between Store and Load. There are two types of barriers. A compiler barrier prohibits any code motion optimization; it is strictly a compiler directive, and it does not generate any code. A full memory barrier avoids reordering instruction not only in compiling time but also in execution time. Whereas full memory barrier is stricter, it has higher impact on the application performance. A possible technique to avoid full memory barrier is promoting compiler barrier

on demand when the writer needs to update the shared object (Desnoyers, 2012). Signal based RCU is a kind of synchronization that exploits compiler barrier, while general purpose RCU uses full memory barrier. An experiment with empty critical section has been performed to observe the performance of both algorithms. As Figure 10 shows, signal-based RCU outperforms general purpose, thanks to compiler barrier.

MESSAGE PASSING

Message passing is a communication technique among threads in multi-threaded programming and it is appropriate for synchronization mechanisms. Message passing cost is the overhead of communication messages among the threads. There are different methods to send messages between threads such as socket, pipe, and queue. Since the cost of sending and receiving message is high, CPU designers intend to provide hardware message passing among the cores. Recently, synchronization methods exploit hardware message passing in their mechanisms (Petrović, 2014). CPU

Figure 10. Signal based RCU vs General purpose RCU

manufacturers (e.g., Single- Chip Cloud by Intel and TILEGX by Tilera) provide a mesh between cores which enable programmers to send/receive messages in a fast way.

of all the approaches reduces and converges together.

CRITICAL SECTION LENGTH

The size of critical section has direct impact on the performance of the synchronization algorithm. Studies have proven that performance of different synchronization mechanisms converge with large critical section size (Desnoyers, 2012; Petrovic, 2015). To observe the effect of long critical section, an experiment with different sizes of critical section has been performed on three different synchronization mechanisms. Figure 11 and Figure 12 show the results with a loop of 1,000 and 100,000 iterations in the critical section, respectively. When the size of the critical section increases, the performance

FUTURE RESEARCH DIRECTIONS

The performance of a synchronization mechanism depends not only on the algorithm, but also on how hardware facilities are exploited. It is likely that the future direction in enhancing the performance of the synchronization mechanism regards exploiting new hardware facilities in sophisticated non-blocking algorithms. Message passing, atomic broadcast, prefetching techniques, and atomic operations can be used in modern processor for an advanced synchronization mechanism. The evaluation of the synchronization costs given in this study can help future research in designing a novel software/hardware synchronization algorithm.

CONCLUSION

This study has investigated the costs of synchronization algorithms in parallel environment. The costs of memory access, spinning, system call and hardware support instruction, barrier, message passing and the size of critical section length on the performance of the state-of-the-art approaches have been reviewed and experimental results are presented to support the evaluation. Some good practices are deduced as follows:

- The number of update operations should be reduced because it has a direct impact on the performance of the application.
- If a cache locality technique is used to reduce the number of cache misses, the cost of keeping data locality should not exceed the cost of cache misses.
- A synchronization method without system call or heavy instruction and a non blocking synchronization algorithm lead to a better performance.
- If a synchronization method in shared memory environment is required, choosing a technique with hardware message passing support can increase the performance.
- Since heavy critical section decrease and converge the performance of different synchronization techniques, the critical section length should be reduced as much as possible.

KEY TERMS AND DEFINITIONS

Critical Section: A part of the code that access to the shared object.

Memory Barrier: An operation to avoid the reordering of instructions.

Multicore Architecture: A processor with two or more cores, i.e., independent processing units.

Performance: Number of operations in the unit of measure.

Race Condition: Attempt to read and write a shared object, by more than one thread with an undefined behavior.

Spinning: The act of querying (or in some cases modifying) an object, and waiting till desired content is achieved, before entering into the critical section.

Synchronization: A technique for coordinating threads or processes to have appropriate execution order.

The Future of High-Performance Computing (HPC)

Herbert Cornelius

Intel Corporation EMEA, Germany

INTRODUCTION

High-Performance Computing (HPC) is used to address and solve the world's most complex computational problems. For decades, HPC has established itself as an essential tool for discoveries, innovations and new insights in science, research and development, engineering and business across a wide range of application areas in academia and industry. It has become an integral part of the scientific method – the third leg along with theory and experiment.

Today, High-Performance Computing is also well recognized to be of strategic and economic value – HPC matters and is transforming industries (Osseyran & Giles, 2015).

High Performance Computing enables scientists and engineers to solve complex and large science, engineering, and business problems using advanced algorithms and applications that require very high compute capabilities, fast memory and storage, high bandwidth and low latency throughput, high fidelity visualization, and enhanced networking.

Today, the IT industry is being transformed by cloud, big data, social media, artificial intelligence, and “Internet of Things” technologies and business models. All of these trends require advanced computational simulation models and powerful highly scalable systems. Hence, sophisticated HPC capabilities are critical to the organizations and companies that want to establish and enhance leadership positions in their respective areas.

Some industry verticals and application areas where HPC is used are as follows:

- Manufacturing, Computer Aided Engineering (CAE)
- Automotive Industry
- Aerospace Industry
- Weather Forecast and Climate Research
- Energy, Oil & Gas Industry, Geophysics
- Life-Science and Bio-Informatics (Genomics)
- Government Research Laboratories
- Universities (Academics), Machine Intelligence, Machine/Deep Learning, Artificial Intelligence (AI)
- Astrophysics, High-Energy Physics, Computational Chemistry, Material Science
- Financial Services Industry (FSI)
- Digital Content Creation (DCC)
- Defense
- Security and Intelligence

BACKGROUND

After its initial years of proprietary computer systems in the 1970/1980's, HPC has evolved with industry standards that democratized Supercomputing, making advanced computing available to more users and wider application segments.

Today's modern HPC solutions are utilizing high-performance server compute nodes connected with high performance fabrics connected to high-performance storage systems, mainly deployed on distributed cluster architectures running on Linux based operating systems with up to tens of thousands of processors. For specific workloads and applications with the need for large

coherent shared memory capacity (terabytes of data: TB), more specialized solutions and systems are used based on cc:NUMA (Cache-Coherent Non-Uniform Memory Access) architectures. For example, the SGI UV system supports up to 256 CPU sockets and up to 64TB of cache-coherent shared memory in a single system.

While in the past chip designs used to be limited by space and the number of transistors available, now power consumption is becoming the main constraint for High-Performance Computing. With several new emerging technologies there will be multiple opportunities to address some of the ongoing challenges in HPC such as balanced architectures, energy efficiency, density, reliability, resiliency, sustainability, and last but not least ease-of-use.

As stated in a recent article (Bader, 2016), the trend in high-performance computing (HPC) to adopt more accelerators such as graphics processing units (GPUs), field-programmable gate arrays (FPGAs), and coprocessors has led to significant heterogeneity in computation and memory subsystems. Application developers typically employ a hierarchical message passing interface (MPI) programming model across the cluster's compute nodes for internode communication, and an intranode model (normally based on shared memory) such as OpenMP for the CPUs or an accelerator-specific library (usually based on an off-load model) such as compute unified device architecture (CUDA) or open computing

language (OpenCL) for accelerator devices within each compute node of a cluster.

The following sections will discuss some of the new emerging technologies that are being developed for all parts of HPC to enable balanced solutions regarding data processing (compute), memory, storage, fabric and I/O, as well as parallel software and programming aspects for HPC.

Processing

A modern HPC solution can be characterized by its functional high level components consisting of the following parts as shown in Figure 1:

- **Compute:** Advanced calculations with data in fast memory performing mathematical and logical operations.
- **Processing:** Including data movements, data packing/unpacking, compression/decompression and encryption/decryption of data.
- **Visualization:** High fidelity visualization of results and data, often in-situ.
- **Storage:** fast and high capacity permanent data storage.
- **Fabric:** High performance interconnect to connect all parts of a HPC solution together.
- **Networking:** To provide access to other systems and traditional IT infrastructures.

Figure 1. High level view of HPC solution components

Figure 2. Schematic overview of a HPC Cluster solution

The main HPC solution architecture today is cluster based, consisting of a certain number of shared memory nodes, each with several processors/cores for compute, memory, local storage and networking devices as shown in Figure 2. The cluster nodes are connected together via a high-performance HPC fabric and can be used for a variety of tasks like (parallel) computing, visualization, I/O, storage, networking, login/interactivity and management.

Future HPC systems are expected to continue to deploy enhanced clustering architectures and technologies to achieve scalable high performance in an energy efficient way.

As it is recognized today, the common theme in the industry for high performance and energy efficiency is to utilize more and more parallelism on all computing platforms and at all levels of integration. Thus, in general, a modern HPC solution deploys several levels of parallelism concurrently as shown in Figure 3:

- **Clustering:** Shared memory nodes connected via a high-performance fabric.
- **Multi-Threading:** Across all processors and cores in a shared memory cluster node.

- **Acceleration:** Heterogeneous accelerators (DSP, GPU, FPGA) connected to cluster nodes.
- **Vectorization:** Single Instruction Multiple Data (SIMD) processing within each core.
- **Parallel Instructions:** Instruction Level Parallelism (ILP) inside each core.

On the processor side, multi-core CPUs are being used across the industry. In general, a multi-core processor consists of a number of cores on a single die (chip) with an on-chip interconnect connecting all the cores, memory and I/O-subsystem together, providing a cache coherent shared memory environment. The number of cores inside a multi-core processor have evolved over time to 10-20, and this trend is predicted to increase only moderately in the future. Multi-core processors use a relatively large number of transistors for each core, so those cores are often called “big cores”. Examples of “big core” multi-core processors are Intel Xeon, AMD Opteron, IBM POWER, and SPARC based CPUs, while “small core” examples are ARM architecture based CPUs, normally featuring a lower number of cores with somewhat less performance per core.

Figure 3. Levels of parallelism in modern HPC solutions

A design goal for big core multi-core processors is to achieve high-performance and powerful capabilities for each single core (thread). If the single thread performance of processors continues to increase, then applications will continue to execute faster. However, an important factor in single thread performance is the processor's clock frequency, and that has plateaued in recent years. This is because the chip's power requirement increases with the cube of the clock frequency ($Power \propto Frequency^3$), and the frequency of today's processors are limited by this equation.

In recent years the industry has extended the concept of multi-core to many-core processors

by integrating more and more "small" cores onto a single chip. Though each core utilizes fewer transistors and runs at a lower frequency, but the aggregated processing power of such a large number of cores exceeds the processing power of a multi-core processor of similar size and power consumption. An example of a general purpose many-core processor is the Intel Xeon Phi 2nd generation (code name Knights Landing) with up to 72 cache coherent cores connected by a 2D-mesh on-chip interconnect. Examples of special purpose many-core processors are GPUs and DSPs with large numbers of simple specialized execution units.

Figure 4. Multi-core processor chip (left) and many-core chip (right). Images not to scale (Source: Intel)

Actual chip die photos of a general purpose multi-core and many-core processor are shown in Figure 4.

The trend to more and more cores per processor chip will continue, mainly driven by power constraints and improvements of the manufacturing process which continues to allow the integration of more and more transistors into smaller and smaller chips. The state-of-the-art volume logic process technology today is 14nm with 3D-gate and FinFET technologies moving to 10nm soon, and the industry projection is that it should be possible to go down to about 5nm structures in the future (Waldrop, 2016).

In order to increase performance and keep power consumption low, new core architectures and additional capabilities are being developed and implemented. Besides using more cores, one of the technologies in this area for data level parallelism is Single Instruction Multiple Data (SIMD). This performs the same operation on multiple data elements simultaneously. Examples for SIMD implementations are the Intel SIMD instruction set extensions (MMX, SSE, AVX, AVX2, AVX-512), AMD 3DNow!, IBM AltiVec, SPARC VIS, and as well as ARM's NEON and the recently announced SVE (Scalable Vector Extension) technology for ARMv8-A architecture based processors. It is projected that SIMD technologies will be enhanced and continue to be an important part of future HPC focused processors.

In addition the industry continues to explore on-going improvements in the area of cache technologies to keep data close to the cores for fast access, out-of-order execution and parallel superscalar execution to perform as many instructions and operations concurrently as possible (Instruction Level Parallelism: ILP).

Because of the ever-increasing demand for more performance in HPC, people have always considered additional acceleration technologies to augment general purpose computing solutions. For specific and suitable workloads and algorithms, accelerators can indeed deliver higher performance with lower power, increasing the performance/watt

ratio – which means higher energy efficiency. Such accelerators are usually provided by PCI Express (PCIe) add-in cards installed in some of the compute or I/O cluster nodes. Traditional accelerators include Digital Signal Processors (DSPs) and Graphics Processing Units (GPUs), each with its own programming model and programming language. With advancements in technology, Field-Programmable Gate Arrays (FPGAs) are emerging with high energy efficiency and high performance to go beyond the capabilities of GPU and DSP acceleration. For example, Altera's 14nm Stratix 10 FPGA is capable of 10TFLOPS peak performance (single-precision IEEE-754) and delivering up to ~100GFLOPS (FP32) performance per watt, and future FPGA products from Xilinx are also expected to deliver higher performance and increased energy efficiency.

In the past, FPGAs have been difficult to program, but now they use modern programming models like OpenCL (and potentially OpenMP in the future) allowing them to be used more easily, harnessing the full performance potential of a flexible and freely re-programmable accelerator. It is projected that it will be possible to integrate FPGAs more tightly with general-purpose processors to eliminate the PCIe bottleneck of the FPGA add-in cards to provide more features and more capabilities such as shared virtual memory between CPUs and FPGAs. Microsoft's project Catapult is a recent example of how modern FPGAs can be integrated to accelerate particular computational tasks (Wired, 2016).

For some more specific workloads custom ASICs – explicitly designed to fit the specific needs – might be a reasonable solution for high performance and energy efficiency, but they are not reconfigurable devices that can be programmed and adopted to evolving requirements. An example of such a solution is Google's Tensor Processing Unit (TPU), a custom ASIC built specifically for its TensorFlow machine learning framework, and the planned specific ASIC for deep learning by Intel utilizing its acquired Nervana technology.

Figure 5. Illustration of an evolving new memory hierarchy (not drawn to scale)

This trend is also outlined in a recent IEEE article (Moore, 2016) about other types of hardware accelerators. “We have to improve performance by improving energy efficiency. The only way to do that is to move some software to hardware. The challenge is to figure out which software is used frequently enough that we could justify implementing it in hardware,” he (Yan Solihin, NC State) says. “There is a sweet spot.”

Other new evolving technologies and designs being researched are Quantum Computing (D-Wave), Cognitive and Neuromorphic Computing (IBM and its TrueNorth chip), and HPE’s “The Machine” project utilizing a memory centric system architecture approach rather than a more traditional compute centric design point.

It is clear that parallelism and heterogeneity will play a major role in future HPC solutions, for both performance and energy efficiency reasons. See (Zahran, 2017) for a good overview on this subject.

Memory, Storage and I/O

It is well recognized that memory performance is evolving at a slower pace than compute performance. This increasing unbalance poses an ongoing challenge for balanced HPC solutions. There is an urgent need to develop new memory technologies and architectures to allow higher

performance and eventually also higher memory capacities. Fortunately, several new memory technologies are being developed and will become available in the near future to overcome the respective roadblocks.

While traditional DDR memory like DDR4 will continue to be present in HPC solutions for some time, it is not clear yet if and how a potential next generation of DDR memory (likely to be called DDR5?) will look like and what its future timeline might be.

Modern memory hierarchies already utilize several levels of data caching to mitigate the performance differences between processing and memory, some implementations go up to 4 levels of private/shared caches. In addition sometimes additional memory buffers are used to speed-up DDR based memory performance for both latency and bandwidth.

It is envisioned that in the future the single monolithic DDR memory subsystem will be complemented - or even be replaced over time – by a combination of somewhat lower capacity but much higher bandwidth memory closer integrated to the CPU and much larger capacity but lower bandwidth non-volatile memory (NVM); see Figure 5.

For the high-bandwidth memory part several approaches are being developed by the industry like Hybrid Memory Cube (HMC), High-Band-

width Memory (HBM), and Multi-Chip DRAM (MCDRAM: 3D stacked DDR memory). A high-bandwidth memory could be used as explicit managed memory or as transparent cache to DDR/NVM memory, its initial capacities are projected to be a few gigabytes (GB) with hundreds of gigabytes per second bandwidth.

The new non-volatile memory 3D XPoint technology, jointly developed by Intel and Micron, will allow to use it for non-volatile memory DIMMs (byte addressable) as well as in SSDs for I/O block devices (see below) for fast storage (Figure 6). A key feature of this technology is higher performance in general and specifically a dramatically improved latency and endurance compared to today's NAND (Flash) based NVM technologies, up to 1000 times higher on the technology level. It will allow users to do things with storage that are fundamentally different from what have been done before. Other new technologies under development in this area are Hybrid Memory Cube (HMC) by Micron, Memristor driven by Hewlett-Packard Enterprise, High Bandwidth Memory (HBM) by Samsung and SK Hynix, Phase Change Memory (PCM) by IBM and 3D-ReRAM by Toshiba/Western Digital. Those technologies are also sometimes referred to as Storage Class Memory (SCM) because they can be used for both memory (byte-addressable load/store) and for storage (block-I/O read/write) solutions.

Going beyond and away from traditional DDR memory, there is also the idea of what is called

“Universal Memory”, a single layer of persistent (non-volatile) memory that can provide much increased memory capacities with low latencies, high bandwidth and enough performance to support the emerging memory and data driven computing environments. All before mentioned NVM technologies are potential candidates for new server memory solutions in the future.

Also on the storage side there is a need to improve performance to have balanced HPC systems. Using PCI Express 3.0 based I/O interfaces, the delivered performance is reasonable good depending on how many I/O lanes are utilized. PCI Express 3.0's 8 GT/s bit rate delivers up to 985 MB/s per x1 lane. In HPC it is very common to use x4, x8 or x16 PCIe 3.0 based I/O devices such as accelerators, SSDs and fabric. The integration of PCIe lanes directly into the processor also helped speeding up I/O. The industry is currently working on the next generation PCIe 4.0 specification for a 16 GT/s bit rate per lane, thus doubling the bandwidth of PCI Express 3.0 and maintaining backward compatibility. The final industry standard specifications of PCI Express 4.0 are estimated to be available in the 2017 timeframe.

The benefits of Solid State Drives (SSDs) over Hard Disk Drives (HDDs) for storage are already proven for multiple reasons such as much higher performance (higher bandwidth, lower latency, more IOPS), energy efficiency and better robustness due to missing moving parts of an HDD. SSDs typically use flash memory based on

Figure 6. Illustration of 3D XPoint (left) and 3D-NAND technology (right). Images not to scale (Source: Intel and Micron).

Figure 7. Schematic overview of a Burst Buffer architecture concept

NAND technologies to permanently store data (non-volatile, persistent). While today's SSD capacities can go up to 16TB using 2D/3D-NAND technologies and being well on par with HDD capacity, emerging newer 3D-NAND technologies (Figure 6) will enable SSDs to increase its capacities dramatically, and potentially overtake HDDs in capacity in the future. To get additional performance especially for PCIe based SSDs, the Non-Volatile Memory Express (NVMe) protocol was introduced a few years ago, improving both random and sequential performance by reducing latency, higher levels of parallelism, lower overhead and optimized control flow.

Furthermore, from a HPC system architecture point of view the concept of an I/O and storage Burst Buffer is emerging, initially around the widely used high performance global parallel file system Lustre. The idea of a Burst Buffer is to use it as a layer of (fast) non-volatile NVM storage that is located between the processors' memory and the parallel HPC file system, serving to accelerate I/O and storage performance of an HPC solution. The overall concept of a Burst Buffer is shown in Figure 7.

To further improve the I/O performance of server attached devices, there are several recent new industry initiatives being formed to define improved interfaces.

One of them is OpenCAPI, an open-standard and high-speed interface for connecting external devices to server systems. According to current

plans, OpenCAPI is targeted to deliver up to 25 gigabits per second per lane, which makes it three times faster compared to PCIe Gen3 and one and a half times faster than PCIe Gen4 (planned to be introduced during 2017). Furthermore, OpenCAPI is designed to allow attached devices to directly access system memory the same way as a respective CPU.

Another initiative in the area of interconnect fabrics is the Gen-Z industry consortium with the following goal: "An open systems Interconnect designed to provide memory semantic access to data and devices via direct-attached, switched or fabric topologies." (genzconsortium.org).

HPC Interconnect Fabric

The hardware "glue" of modern HPC cluster architecture solutions is the Interconnect Fabric which connects all the components together. It is a scalable, end-to-end low latency, high bandwidth and high message rate throughput fabric to allow fast communication and data exchange between all the nodes in a cluster. Originally clusters used Ethernet based interconnects. Current HPC cluster solutions often deploy an InfiniBand based fabric (QDR, FDR or EDR) or a higher performance Ethernet implementation like 10GbE. With the new Omni-Path Architecture Intel has recently introduced an advanced HPC cluster fabric based on the Cray Aries interconnect protocol to overcome some of the inherent limitations of

InfiniBand for performance, reliability and scaling. Today, all high-end fabrics (EDR InfiniBand, Intel Omni-Path and 100Gb Ethernet) are utilizing 100Gbs links and are projected to double the bandwidth with the respective future generations' implementation in the future, e.g. Mellanox HDR InfiniBand at 200 Gbit/s, and larger switch sizes. Such new technologies will likely be utilizing Software Defined Networking (SDN) functionalities, allowing flexible system configurations and fabric topologies like hypercube, dragonfly, and multi-dimensional tori. Additional features of a modern HPC fabric include (hardware) RDMA, MPI tag-matching, off-load and virtualization support functionalities. The OpenFabrics Alliance (OFA), an open source-based organization, provides the standard fabric APIs for HPC fabrics.

For high-performance and mid- to long-range communication and I/O in the data center, Silicon Photonics (SiPh) technology based solutions are about to become available in the market. SiPh will be extremely beneficial for architecting very large HPC clusters deploying 10s-100s thousands processors with a fast optical interconnect fabric for low end-to-end latency and high throughput and bandwidth. Silicon Photonics is combining two very different technologies - electronics and photonics - in the same silicon chip and has been a high hurdle to overcome in the past. Optical (light based) interconnects will address the bandwidth bottleneck inherent in the (copper) wires and can take full advantage of the improvements in processor speed and capabilities. In addition, SiPh is also very energy efficient. Thus, the combination of Silicon Photonics with new optical cables (e.g. Corning Clearcurve) enable massive data rates of up to 1.6 terabits per second at lengths up to 300 meters. It extends high speed connectivity from 3 meters to 2 kilometers, facilitates higher density arrays, enables integration of communications into silicon and efficiently scales line rate speeds and throughput – all in a single integrated chip (see Figure 8 for illustration).

Today, SiPh transceivers are available as an alternative to the conventional VCSEL technol-

ogy. In the future, SiPh will enable higher levels of functionality to be integrated into the optical interface. The initial bandwidth of SiPh based networking is supposed to be 100Gbit/s with plans to increase it to 400Gbit/s in the future. Companies actively working today on Silicon Photonics technologies for example are Intel and IBM.

Emerging HPC Workloads and Delivery Models

Traditional HPC workloads are evolving and growing, becoming more complex, and requiring more performance. However, HPC workloads are changing as well - not that traditional HPC is disappearing, but there are new workloads being added. One of the fastest emerging areas for HPC is High-Performance Data Analytics (HPDA): Big Data (Analytics) using HPC. This is due to the increasing need to extract intelligence (both scientific and business) and value out of massive data sets based on complex data analytics technologies (neural networks, deep/machine learning, data clustering, predictive modeling, data categorization, etc.) requiring data intensive computing. The projected evolution for data analytics is going to cognitive computing and further on to neuromorphic computing in the future: turning data into actionable insights.

Beyond the traditional applications of HPC, new application areas are emerging based on the

Figure 8. Silicon Photonics prototype (Source: Intel)

Internet of Things (IoT). The IoT is a huge source of data, and extracting value from this data requires HPC-like techniques to capture, store, filter, process and analyze at a scale which is similar to some of the largest HPC science projects such as the Large Hadron Collider (LHC) at CERN and the planned Square Kilometer Array (SKA).

We can already see that HPC and Big Data Analytics are merging together using advanced technologies such as machine learning and deep learning. Because of the sheer amount of data and the compute power required to process the data, one can benefit from HPC technologies (hardware and software) and HPC solutions in the future to handle these increasingly complex data processing environments efficiently. The importance of IoT can be seen in the recent Forbes article (Forbes, 2016) that “IDC estimates the direct Internet of Things (IoT) market will grow to more than \$1.7 trillion by 2020.”

All of the above new areas for HPC will enhance scientific, engineering and business (compute and simulation) capabilities, especially when combined with advanced Artificial Intelligence (AI). However, with this also comes the need for more consideration of ethical constraints when applying emerging Artificial Intelligence technologies. Current AI is used to augment human capabilities, and support people to do things better. All these new technologies should be developed, deployed and adopted in a responsible, ethical and enduring way.

One of the more traditional access mechanism to HPC capabilities is Grid Computing, it combines computer resources from different domains – often geographically dispersed and opportunistically – to spread tasks across multiple computers interconnected by a communication network. This approach is mainly used for the type of “farming” workloads where the distributed tasks are independent of each other, do not communicate tightly together and latency is not important. An example of such a Grid is the Worldwide LHC Computing Grid (WLCG) project, a global collaboration of more than 170 computing centers

world-wide in 42 countries, linking up national and international grid infrastructures.

Delivery mechanisms for HPC are also changing: HPC in the Cloud is an emerging trend. It includes different implementations from private to hybrid to public cloud environments and infrastructures; see Figure 9 for illustration. As with many new technologies and solutions, there are both challenges and opportunities. On the opportunity side, HPC in the (public) Cloud enables more people and companies to benefit from HPC to gain more and better insights and knowledge, as well as to start using HPC in new ways. This is particularly true for public Clouds being used by small to medium sized manufacturers who do not have access to HPC today or have only temporary needs for it. In some sense it actually helps democratizing HPC. HPC in the Cloud can also be used for ad-hoc peak demand “offload” to augment in-house HPC capacity. There are already companies offering specialized HPC in the (public) Cloud solutions like the company Rescale, but also traditional Cloud hosting companies like Amazon Web Services (AWS) and Microsoft Azure provide certain HPC focused Cloud instances. Also in this area cloud brokering services and marketplaces are emerging, for example UberCloud and Cycle Computing. Some of the challenges for public Cloud usage are considerations around the following topics, but they are not limited to HPC: data movement volume, bandwidth and delays; security and compliance concerns; data protection, privacy and security; risks and liability concerns; legal regulations; and certainly service level agreements (SLA), predictability, business continuity and total cost of ownership (TCO) – especially for transferring data in and out of a Cloud environment.

On the other hand, private HPC Cloud infrastructures (often implemented on-premise) allows organizations to transform, complement or extend their HPC environment to a more elastic resource pool. A private HPC Cloud solution allows organizations to keep all their data under their own control and follow any required policies. In the

future these solutions may be implemented on top of a Software Defined Infrastructure (SDI), offering the potential to optimize overall HPC compute infrastructures, reduce TCO, achieve more flexibility, increase productivity, and gain higher operational and business efficiencies.

In this context, virtualization is gaining more momentum for HPC workloads in form of Linux Containers (e.g. Docker), especially targeted for high-performance environments and applications like the Singularity (Lawrence Berkeley National Laboratory, LBL) and Shifter (National Energy Research Scientific Computing Center, NERSC) projects.

HPC Software

With all the new parallel technologies being implemented in hardware, there is an increasing need for Software Modernization – enabling software to take full advantage of all available parallel performance capabilities in the hardware in a scalable manner. The goal here is to develop and implement software and applications in a way that is portable, re-usable and sustainable in the future, while at the same time deliver high performance and scalability to utilize ongoing improvements in hardware. The ideal result would be that when hardware

advances the software doesn't have to change to take advantage of increased performance. This can be done by using industry standard higher level programming models and languages, software tools and techniques, and optimized libraries for the respective architectures. Examples of this are vectorization (using SIMD), shared memory multi-threading (task parallelism) via OpenMP, heterogeneous parallel acceleration via OpenCL and explicit message passing via MPI or Distributed/Virtual Global Shared Memory interfaces like partitioned global address space (PGAS). In addition, new parallel programming models and languages are being explored on all levels for ease-of-use, scalability and high-performance. A comprehensive overview of modern parallel programming models and languages for parallel computing is provided by Balaji (2015).

Because of the ability of HPC solutions to crunch a lot of data fast and supporting the rapidly growing “Big Data” use cases, there is an increasing need for high-fidelity visualization of very large data sets (often in-situ). For this, open source Software Defined Visualization (SDVis) based frameworks are emerging to allow better and faster high-quality (in 3D) immersive visualization of large and complex data sets not possible with standard graphics hardware (see Figure 10). Be-

Figure 9. Emerging HPC delivery models via Cloud infrastructures

cause such solutions are implemented in software, they can be optimized to fully utilize the compute power and capabilities of modern HPC solutions.

Open Source software is pervasive and drives innovation in the industry faster. At the annual Supercomputing 2016 conference, the HPC community announced the OpenHPC initiative, a collaborative, community effort to provide system software building blocks for HPC systems freely available for open source distribution. This industry activity will help making the deployment, management and operation of (Linux based) HPC solutions quicker, easier and more stable, and improve interoperability.

FUTURE RESEARCH DIRECTIONS

As already mentioned before, there are several ongoing challenges in HPC that need to be solved. They include aspects such as balanced architectures at scale, extreme scalability, high energy efficiency, improved density, higher reliability and resiliency, as well as ease-of-use, sustainable software and scalable parallel programming. Intensive research and development is already ongoing to address all of it – and with challenges there are always opportunities.

The areas listed before are of specific interest when looking at the next frontier in HPC: ExaScale computing. It was envisioned that an EFLOPS (ExaFlops: 10^{18} floating-point operations per second - one billion billion operations

of 64-bit double precision) capable system could potentially be built sometime in the 2020s within a power envelope of about 20MW (Hsu, 2016) but not more than 30MW. Recent evaluations of technologies have pushed this goal out more likely to 2021-2023 for delivery of such an ExaScale system, and first machines might feature more novel system architectures. A real ExaScale system is expected to deliver true capabilities and must be suitable for a wide range of different applications and application areas. For a meaningful ExaScale system one will need to archive fifty times more sustained (production) application performance than is available in 2016/2017 – at about the same power consumption level.

It should be noted that theoretically an EFLOPS system could be assembled and operated today in 2016 – but only at ridiculous costs and effort. We will also see much tighter co-design approaches of hardware and software for future HPC solutions, similar to what is already happening in all parts of the IT industry, because software and applications will run most efficiently on hardware that is tuned for it.

CONCLUSION

High-Performance Computing matters and its future is pretty bright. New and exciting technologies are being developed and implemented to address the challenges ahead for HPC, including the way HPC solutions are being architected and new

Figure 10. Emerging Software Defined Visualization: Workflow moving into the data center

emerging HPC use cases. In general, advances are always driven from an application perspective – and going forward the application span is broadening. HPC’s next frontier, EFLOPS (ExaFlops: 10^{18}) computing in a ~20MW power envelope, is certainly of interest from a pure performance and capability point of view. However, maybe even more important are the technologies that are being developed to enable EFLOPS computing, as they can potentially be applied and scaled down to smaller HPC solutions to allow powerful and energy efficient PFLOPS (PetaFlops: 10^{15}) systems consuming only ~20KW, and eventually TFLOPS (TeraFlops: 10^{12}) implementations within a ~20W power envelope.

1.000.000.000.000.000.000 operations per second - imagine what such HPC based solutions could do to advance mankind!

KEY TERMS AND DEFINITIONS

Cluster: A computer cluster consists of a set of loosely or tightly connected computers (nodes) that work together so that, in many respects, they can be viewed as a single system, controlled by software.

CPU: Central Processing Unit, a general purpose integrated circuit chip, the brains of a computer where most calculations take place.

DDR: Double Data Rate, a type of volatile DRAM memory using both the falling and rising edges of the clock signal.

DDR4: Latest generation of DRAM memory technology.

DRAM: Dynamic Random Access Memory, a memory chip that depends upon an applied voltage to keep the stored data.

DSP: Digital Signal Processing, refers to various techniques for improving the accuracy and reliability of digital communications, also used for acceleration of regular structured simple parallel computational tasks.

FPGA: Field-Programmable Gate Array, an integrated circuit designed to be configured and re-programmed by a customer or a designer after manufacturing.

FLOPS: Floating-Point Operations per Second, a performance unit for computer processing capabilities.

GFLOPS: Gigaflops, 10^9 floating-point operations per second, a compute performance unit.

GPU: Graphics Processing Unit, a single-chip special purpose processor primarily used to manage and boost the performance of video and graphics, also used for acceleration of regular structured simple parallel computational tasks.

HDD: Hard Disk Drive, a data storage device used for storing and retrieving digital information using rapidly rotating disks (platters) coated with magnetic material.

HPC: High-Performance Computing, solving the world's hardest computational problems.

ILP: Instruction Level Parallelism, a mechanism to execute several processor instructions concurrently for higher instruction throughput and higher performance.

IOPS: Input/Output Operations per second, a data I/O performance unit.

IoT: Internet of Things, a network of physical objects that feature an IP address for internet connectivity, and the communication that occurs between these objects and other Internet-enabled devices and systems.

KW: Kilo Watt, one thousand watt unit of power.

MPI: Message Passing Interface, a library specification for message-passing between cluster nodes to program parallel applications.

MW: Mega Watt, one million watt unit of power.

NAND: Negative-AND logic gates based flash memory type of non-volatile storage technology that does not require power to retain data.

NVM: Non-Volatile Memory, a type of persistent computer memory that can retrieve stored information even after having been power cycled (turned off and back on).

OpenCL: Open Computing Language, a programming framework for writing software that execute across heterogeneous computing platforms.

OpenMP: Open Multi-Processing, an application programming interface that supports multi-platform shared memory multiprocessing programming used to program parallel multi-threaded software.

PFLOPS: Petaflops, 10^{15} floating-point operations per second, a compute performance unit.

PCI: Peripheral Component Interconnect, a standard for connecting computers and their peripherals.

SDI: Software Defined Infrastructure, a computing infrastructure entirely under the control of software with no operator or human intervention.

SIMD: Single Instruction Multiple Data, a technology to perform the same operation on multiple data points simultaneously to exploit data level parallelism.

SSD: Solid-State Disk, a data storage device containing non-volatile memory technology.

TFLOPS: Teraflops, 10^{12} floating-point operations per second, a compute performance unit.

High-Performance Reconfigurable Computing

Mário Pereira Vestias

Instituto Politécnico de Lisboa, Portugal

INTRODUCTION

High-Performance Reconfigurable Computing (HPRC) systems integrate reconfigurable technology in the computing architecture to improve performance. System designers and engineers of HPRC systems are aware of the potential speed up that can be achieved by integrating Field Programmable Gate Arrays (FPGAs) or other reconfigurable devices in their multiprocessing systems. Besides performance, reconfigurable hardware devices also achieve lower power consumption compared to General-Purpose Processors (GPP), a major advantage given the high power consumption of existing HPC machines. Better performance and lower power consumption could be achieved using Application Specific Integrated Circuit (ASIC) technology. However, ASICs are not reconfigurable, turning them application specific. Reconfigurable logic becomes a major advantage when hardware flexibility permits to speed up whatever the application with the same hardware module. The first and most common devices utilized for reconfigurable computing are fine-grained FPGAs with a large hardware flexibility. To reduce the performance and area overhead associated with the reconfigurability, coarse-grained reconfigurable solutions have been proposed as a way to achieve better performance and lower power consumption. In this chapter we will provide a description of reconfigurable hardware for high performance computing.

BACKGROUND

High-Performance Reconfigurable Computing (HPRC) is a computing paradigm that combines

reconfigurable-based processing (e.g., FPGA technology) with general purpose computing systems, whether single general purpose processors or parallel processors. The idea is to introduce hardware flexibility to accelerate computationally intensive tasks and therefore to achieve higher performance computing compared to platforms without reconfigurable hardware. These systems not only potentially improve the performance relative to non-reconfigurable general-purpose computing systems but also reduce the energy consumption. Saves of up to four orders of magnitude in both metrics are reported for some compute intensive applications (El-Ghazawi, 2008). Almost all HPC vendors provide HPRC solutions materializing their beliefs in the capacities of reconfigurable computing as accelerators for high-performance computing.

The first commercial reconfigurable computing platform for high-performance computing was the Algotronix CHS2x4 (Algotronix) consisting of an array of 1024 processors and 8 FPGAs with 1024 programmable cells each. This architecture was followed by many other reconfigurable proposals for HPRC.

A major concern in the design of HPRC systems is how reconfigurable computing is connected to the non-reconfigurable computing side, whether general-purpose computing or dedicated computing (e.g. general purpose processors or ASICs). A few alternatives exist with different expected performances, cost and flexibility. The typical approach is to consider reconfigurable systems, generally FPGAs, mounted in a board that is connected to the main system using some serial bus to operate as a coprocessor. The approach has a

relative low cost but has a severe limitation from the serial communication between the host and the coprocessors whose bandwidth determines that for the architecture to be computationally efficient the computation to I/O ratio must be high. To improve the co-processing solution, a few architectures have implemented direct point-to-point connections among the co-processors. This speeds-up the communications between reconfigurable co-processors but keeps the communication bottleneck between the host system and the co-processing system. Some works have refined the communication between the host and the FPGA co-processors through a dedicated network interface. A well-known example of this architecture is Cray XD1 (Cray Inc., 2006). To speed-up even more the communication between the host CPU and the reconfigurable units, all units can be connected to a single communication network, like a shared memory system. In this case, all processing units see each other as part of a unique architecture with access to shared memories (SGI RASC RC100 blade from Silicon Graphics).

Another dimension in the architectural design of HPRC systems is the granularity of the reconfigurable platform. The granularity of a reconfigurable system is the smallest reconfigurable functional unit. In terms of granularity they tend to be defined as fine-grained or coarse-grained. Raw FPGAs are fine-grained since they can be

reconfigured at the bit level. Coarse-grain architectures consist of arrays of coarser units, like arithmetic logic units that are reconfigurable at the word level. Coarse-grained architectures are more amenable to design and reconfigure but are less flexible than fine-grained architectures. When the application to run in the reconfigurable architecture can be bit-level optimized then fine-grained architectures are usually more adequate than coarse-grained architectures achieving faster solutions. On the other side, coarse-grained architectures are faster and more efficient when running word-level applications.

Formally, we define fine-grained HPRC as those platforms that use fine-grained reconfigurable logic and coarse-grained HPRC as those systems that try to improve the performance and power consumption of reconfigurable systems by increasing the granularity at which operations are computed.

HIGH-PERFORMANCE RECONFIGURABLE COMPUTERS

In this section HPRC, examples of fine and coarse-grained reconfigurable computing architectures are described in the context of high performance computing.

Fine-grained high-performance reconfigurable computers consist of basically one or more FPGAs

Figure 1. Cray XD1 chassis

for hardware acceleration combined with general-purpose systems. Well-known fine-grained HPRC includes Cray XD1 (Cray Inc., 2006), SRC MAPstation (SRC Computers), Starbridge Hypercomputer (Starbridge Hypercomputers), SGI RASC RC100 blade (Silicon Graphics), Novo-G (George, Lam, & Stitt, 2011), Maxwell (Baxter, 2007), Convey HC-1 (Brewer, 2010), (Bakos, 2010) and Convey HC-2 (Convey Computer, 2011).

Cray XD1 consists of multiple general-purpose processors combined with multiple FPGAs in a set of chassis. Each Cray XD1 chassis consist of up to six compute blades and a blade has two AMD Opteron 200 processors and one Xilinx Virtex-II Pro FPGA. Therefore, a single chassis consists of twelve processors with up to 8 GBytes of memory for each processor and six FPGAs (see figure 1). Each processor has 1 or 2 RapidArray links connected to a non-blocking RapidArray fabric switch. The switch provides up to 96 GB/s of total bandwidth.

The application must be manually partitioned between hardware running on the FPGA and software running on the Opteron processors.

The SRC MAPstation has a board with a dual Xeon processor, a MAP®-C processor and a shared memory of 8 GByte connected with a SRC 4-port switch with a transmission capacity of 1.4 Gbyte/s (see figure 2).

The reconfigurable block, the MAP®-C module, contains one FPGA that controls the access to the dual-port memory with six banks and two Virtex-2 6000 FPGAs for user logic configuration. The control FPGA provides an interface between the SRC 4-port switch and the MAP-C module. The dual-port memory has six banks each with 4 Mbytes 64 bits wide. All six banks are available to the user FPGAs but not at the same time. Transfers between both user logic FPGAs can be operated over one dual-port memory with 4 Mbytes.

The Starbridge Hypercomputer consists of a PC that controls a set of independent processing modules consisting of a Virtex-2 6000 FPGA and 2 Gbytes of local memory. The communication between the PC and the FPGAs (hypercomputer) is through a 64 bits PCI bus running at 66/100 MHz.

The SGI RASC RC100 blade consists of two Virtex-4 LX 200 FPGAs, each with 40 Mbytes

Figure 2. SRC MAPstation

of SRAM. The blade connects to the SGI ALTix 4700 host system through a NUMalink interconnect capable to achieve 6.4 Gbytes per second of bandwidth.

Maxwell is a general-purpose FPGA super-computer. It comprises five IBM BladeCentre chassis. Four of the BladeCentres have seven IBM Intel Xeon blades and the fifth has four. Each blade has a 2.8 GHz Intel Xeon with 1 GByte of main memory and two FPGAs connected through a PCI-X. Each FPGA has access to 512 or 1024 Mbytes of external memory and four Rocket IO connectors delivering each 3.125 Gbps. All 64 FPGAs are connected with a 2D torus interconnection network.

Novo-G is a supercomputer architecture consisting of 24 computing nodes. A node has a Linux server with an Intel quad-core Xeon processor. These nodes communicate via Gigabit Ethernet and 20 Gbps InfiniBand. Each node has also two PROCStar-III boards each containing four Startix-III E260 FPGAs from Altera. This gives a total of 192 FPGAs. Each FPGA has 4.25 Gbytes of dedicated memory and adjacent FPGAs can communicate via a bidirectional bus at rates of 25.6 Gbps.

Convey HC-1 consists of a 2.13 GHz dual-core Intel Xeon with a memory capacity of 128 GBytes and a 1066 MHz front side bus to connect to a coprocessor board. The coprocessor board has four Virtex-5 LX330 FPGAs with 64 GBytes of memory. These four FPGAs connect to eight memory controllers through a full crossbar. The FPGAs are also connected in a ring configuration with a bandwidth of 668 Mbps, full-duplex. Recently, Convey has launched the newest HC-2 (and HC-2ex) server architecture. The new architecture uses the recent Xeon X5600 processor and Xeon E5-2600. Versions with 4, 6 and 8-cores were implemented. The co-processor board has kept the Virtex-5 FPGAs of HC-1 but upgraded to Virtex-6 FPGAs for the more performant HC-2ex architecture. The memory capacity of the main board was upgraded to 192 GBytes of memory. Both HC-1 and HC-2 are not machines for floating-

point executions. The FPGA coprocessors are designed to accelerate data-intensive applications like genome sequence alignment.

Fine-grained high performance reconfigurable computing architectures all use FPGAs to implement reconfigurable logic. They basically differ in how the FPGAs are connected to the general-purpose processors which determines the bandwidth available for the communication between the general-purpose system and the reconfigurable system. Recently, System-on-Chip FPGAs have been introduced (ZYNQ, 2011), (Altera SoC FPGAs, 2012) which integrates an ARM processor with reconfigurable logic connected through high-speed ports. This is a tight integrated of hardware and reconfigurable software that permits the design of very efficient hardware/software solutions for high-performance computing and high-performance embedded computing. Recently (2015), Intel Corp. agreed to buy Altera Corp. to provide heterogeneous solutions based on general-purpose CPUs and reconfigurable logic FPGAs.

FPGAs work at bit-level granularity. Therefore, to support multi-bit operations many resources are needed degrading the area efficiency of a computing system based on FPGAs. Also, there will be a high routing overhead which will considerably reduce the performance of the implemented operations. FPGAs also require large amounts of configuration data increasing very much the configuration time and the power dissipation. To overcome such disadvantages, coarse-grained reconfigurable architectures consider atomic units in the form of 4, 8, 16 or even higher bits wide arithmetic oriented processing units. This permits to achieve greater efficiency executing word-level operations improving the area, the configuration time, the performance and the power consumption compared to fine-grained reconfigurable architectures.

Several coarse-grained reconfigurable architectures (CGRA) were proposed during the last decade. DP-FPGA (Cherepacha & Lewis, 1996) is a coarse-grained architecture oriented to the design of datapaths. It consists of four-bit datapath

width units with a structure similar to that of an FPGA. KressArray-1 (Kress, 1996) is an array of reconfigurable datapath units working in a data-driven fashion consisting of a generalization of the systolic array. Rapid (Ebeling et al., 1996) is a linear array of datapath units designed to work mainly in a computational pipeline optimized to repetitive computation intensive tasks. The units consist of an integer multiplier, three ALUs, general-purpose registers and local memories. MATRIX (Mirsky & DeHon, 1996) is an array of identical 8-bit elements containing each 256 bytes, an 8-bit ALU, a multiply unit and control logic distributed in a 2D-mesh architecture. Raw Machine (Waingold et al., 1997), an array of tiles consisting of instruction and data memory, an ALU, registers, configurable logic and a programmable switch. KressArray-3 (Hartenstein et al., 1999) a mesh of reconfigurable datapath units (rDPU) connected to the four nearest neighbors with bidirectional links with a datapath width of 32 bits. Each PE can be configured to run integer operators. MorphoSys (Lu, 1999) is a more elaborate architecture with a core processor, a context memory, a frame buffer, a DMA controller and an array of 8×8 reconfigurable cells. Each reconfigurable cell contains an ALU with multiplier, a shifter, and a register file. The ALU can perform a multiply-accumulate operation. PipeRench (Schmit, 2002), consists of a linear array of processing elements for stream computing in a pipelined fashion. Each processing element contains a bank of registers and an ALU implementing bitwise functions, addition and subtraction with eight bits wide.

ADRES (Meiet et al., 2003) is an heterogeneous architecture with a tightly coupled VLIW (Very-Long Instruction Word) processor and a coarse-grained reconfigurable matrix. Each reconfigurable cell consists basically of a register file and a functional unit.

MORA (Lanuzza et al., 2007) consists of a 2D array of configurable cells organized in a 4×4 quadrants connected with a reconfigurable network. The reconfigurable cell contains a dual-port 256 bytes SRAM, an 8-bit ALU and a control

unit. The ALU contains a set of registers, two 8×4 multipliers, and a 16-bits adder. WPPA (Kissler et al., 2006) (Weakly Programmable Processor Arrays) – consists of an array of weakly programmable processing elements (WPPE) with limited instruction memory and optimized control. The instruction set is parameterizable at compilation time. Each WPPE can be parameterized to contain several functional units like adders, multipliers, shifters, and other modules for logical operations. It is also possible to include specific functional units implementing user-defined functions (e.g., a Fast Fourier Transformation). FPOA (Field Programmable Object Array) is a reconfigurable array proposed by MathStar (www.mathstar.com) The array consists of small ALUs organized in a regular structure similar to an FPGA. The device also contains memory and MAC blocks for signal processing The XPP architecture (PACT-XPP) is another coarse-grained architecture containing a 2D array of programmable elements, capable to perform typical arithmetic operations, and a number of internal RAMs. BiRC (Bilkent Reconfigurable Computer) (Atak & Atalar, 2012) is a statically reconfigurable architecture consisting of three types of processing elements, namely an arithmetic logic unit, a memory and a multiplier, displaced in columns and connected to four neighbors.

The above coarse-grain architectures improve the performance of integer operations, but have little advantage over fine-grain reconfigurable logic when floating-point operations are required. Recent works have proposed coarse-grain reconfigurable architectures with dedicated support for floating-point operations. For example, FloRA (Lee et al., 2009) is a coarse-grain reconfigurable architecture that performs both integer and floating-point operations. The system contains a RISC processor, a DMA controller, an external memory interface and the reconfigurable computing module. The RISC processor controls all the components in the platform and is also used to execute control-intensive pieces of software. The reconfigurable module contains an array of

processing elements (PE), an execution control unit to monitor the status of the reconfigurable module, a configuration cache and a frame buffer. The PEs are arranged in an array of 8×8 connected to neighbors and contain an integer ALU and 16-bit registers. PEs in the same row share a multiplier, a divider and a square root logic. Floating-point operations are implemented by grouping two PEs. One PE calculates the mantissa and the other calculates the exponent. However, the architecture only implements a custom floating-point format with 8 bits for the exponent and 15 bits for the mantissa.

Another approach to support floating-point reconfigurable computing was proposed in (Ho et al., 2009). The floating-point FPGA (FPFPGA) is a fine-grained FPGA with dedicated columns with reconfigurable coarse-grained units containing fixed-function floating-point adders and multipliers and general-purpose bit blocks all connected with unidirectional buses. The floating-point units support both 32 and 64-bits floating-point format.

The new generation 10 FPGA from Altera (2015) provides hardened floating-point blocks. These new devices integrate coarse-grain arithmetic blocks with fine-grained logic in a single device providing up to 10 TFLOPs of peak performance in a single device that can be configured at fine granularity.

More recently, some new directions for coarse grain reconfigurable arrays were proposed. EGRA (Expression-Grain Reconfigurable Architecture) (Ansaloni, Bonzini, & Pozzi, 2011) consists of an array of cells where each cell is a group of arithmetic logic units. They call it coarse grain cell RAC (Reconfigurable ALU Cluster). Inside a RAC, ALUs are organized in rows connected by switchboxes. The inputs to RACs come from neighbor RACs, from the RAC itself and from constants. The number and functionality of each ALU can be customized by the designer. The cell configurations are stored in a context memory and can be loaded at runtime. The EGRA array is a mesh of cells that can be RACs, memories or multipliers. As most of the CGRA architectures,

EGRA does not have support for floating-point operations. SYSCORE (Patel, McGettrick, Bleakley, & Chris, 2011) is an CGRA architecture for low power, real time processing of biomedical systems. The architecture proposed consists of an array of Configurable Functional Units (CFU) and RoundAbout Interconnect (RAI) units. Data is injected into the array using two input Direct Memory Access (DMA) units and the output data is driven by an output DMA. The CFU has a computation unit supporting MULT-ADD, MULT-SUB and compare operations. The bit width of all units and registers is 24 bits. CFU are connected to neighbor units. Since the CFU are tailored to specific target applications, good performance and energy consumptions were achieved. In (Silva, Fernandes, Véstias, & Neto, 2012) a new architecture for a coarse-grained reconfigurable array targeted to linear algebra problems. The reconfiguration memories are implemented using magnetic tunneling junctions. These storage elements provide for non-volatility and for a very effective implementation of multi-context planes. The proposed architecture is organized as a 2-dimensional mesh of double precision floating-point execution units. The execution units are run-time reconfigurable. Their configurations define the operation to be executed and the data flow intra and inter execution units. The array is organized as a 2D mesh of reconfigurable execution units (REU). The arithmetic unit of the REU has a fused multiply-accumulate operator and a reciprocal/division operator. This Configurable Floating-point Arithmetic Unit (CFAU) currently implements the following 64-bit floating-point operations: addition, subtraction, multiplication, reciprocal, division, fused multiply-add and fused multiply-accumulate. As referred, the reconfigurable memory is implemented with magnetic memory cells and currently supports two planes of context, which can be exchanged within a clock cycle.

All these works provide reconfigurable platforms to execute word-level operations faster than when executed in fine-grained reconfigurable FPGA platforms. All solutions try to innovate the

design of reconfigurable coarse-grain solutions. However, most of them have failed to compete with fine-grained FPGAs (Coudert, 2009). The failure is mainly due to commercial reasons. Innovative start-ups succeeded in a very specific niche of the market but soon are acquired by a stronger company to complement their portfolio of products. Also, these new technologies require some particular way of programming without any standard behind it, making it very hard to be adopted in a standard based industry. All these problems are serious obstacles to find a well-established HPRC system based on reconfigurable coarse-grained architectures.

FUTURE RESEARCH DIRECTIONS

High-performance reconfigurable computing platforms have already shown their potential to speed-up specific computation intensive applications with orders of magnitude improvement in performance, size and cost over traditional HPC systems. HPRC platforms are based on fine-grained reconfigurability which for word-level applications are less efficient. Most works on coarse-grained reconfigurability improve the performance, area and power consumption compared to fine-grained reconfigurability by considering word-level reconfigurable operations. However, coarser-grained architectures are less flexible and become more application oriented. We are not expecting to design a reconfigurable platform very efficient to all type of applications. But even considering specific application domains, finding the most efficient reconfigurable architecture is still an open research problem.

To the present, reconfigurable computing for high performance is generically based on fine-grained reconfigurable devices, because these are available in the form of FPGAs, while coarse-grained architectures have had a very difficult way to find a place in the market.

Whether fine or coarse-grained, there are many challenges to guarantee the widespread adoption

of reconfigurable computing systems in HPC. A very first requirement of HPC is floating-point processing. New HPRC must support the efficient execution of floating-point operations. Up to date, state-of-the-art FPGAs have the potential to implement hundreds of double precision floating-point units, but with low efficiency compared to hardwired solutions. The recent FPGAs from Altera with hardwired floating-point units have brought FPGAs again to the high-performance computing scenario. Some coarse-grained architectures already target floating-point operations. Should FPGAs keep the integer aspects and leave floating-point issues for coarse-grained platforms is an open issue. FPGAs allow also the utilization of dynamic/partial reconfiguration permitting the utilization of virtual hardware, that is, hardware that is configured at runtime due to a lack of space for hardware implementation of the whole hardware architecture.

Other major challenges are under intensive research, including the programmability of the platform and the memory bandwidth improvement. Programmability is a very important aspect since users already have a lot of code and do not want to apply great changes to the code in order to take advantage of the reconfigurable platform. How can the code be ported to the new platform without major investments to rewrite the code? This is a major requirement that the providers of the reconfigurable platforms must answer. Good programming environments already exist, but are very architecture specific. It is important to address portability and maintainability to guarantee the investment on code development. Memory bandwidth is also an important aspect of parallel computing machines and is frequently the main bottleneck of parallel architectures. Adding more processing power into a platform must be followed by more memory bandwidth. Memory architectures must be improved as well as memory bandwidth. Bigger reconfigurable devices allow the use of more memory banks to access external memory and also come with more internal memory that can be used to cache

data inside the reconfigurable device. More has to be done, not only by memory manufacturers, but also by manufacturers of reconfigure devices by, for example, integrating dedicated memory controllers.

FPGA devices are the leading technology for designing HPRC systems. Recent FPGAs manufactured with the top integrated circuit technologies, Ultrascale+ from Xilinx (Virtex) and Stratix 10 from Altera (Altera, 2015), have capacity to achieve TFLOPs (Tera Floating-Point Operations) with access to fast memory interfaces. New SoC FPGAs from Xilinx and Altera already contains a state-of-the-art processor that can be tightly-coupled to reconfigurable logic. Reconfigurable logic in future devices may have a variety of architectures, granularities, etc. It is imperative to keep the research on reconfigurable architectures to look for the most appropriate granularities for HPRC.

New reconfigurable architectures, whether fine or coarse, have to be explored. Fine-grained reconfigurable computing has been preferred mainly due to its availability but there is no evidence that these will be the reconfigurable platforms in the future. Heterogeneous reconfigurable devices with a mix of fine and grain logic should also be explored, like the recent Altera 10 FPGAs. Another research direction is the tight integration of multi-core CPU and FPGA. These heterogeneous architectures integrate the advantages of both devices into a single platform.

CONCLUSION

The article describes the concept of high-performance reconfigurable computing and presents several high-performance reconfigurable computers. Commercial HPRC platforms are based on fine-grained reconfigurable devices (FPGAs). However, coarse-grained reconfigurable computing architectures have shown better efficiency in terms of area, performance, and power consumption. Therefore, it would be expected to see HPRC

platforms based on coarse-grained reconfigurable architectures. However, coarse-grained architectures have failed to compete in the market with fine-grained architectures for several reasons, but mostly due to commercial reasons. So, there have been huge difficulties to have commercial HPRC systems based on coarse-grain reconfigurable computing.

Many application domains will greatly benefit from coarse-grained architectures. For example, many scientific computing applications are very computationally intensive requiring floating-point operations. A coarse-grained architecture with support for floating-point operations would achieve orders of magnitude better performance compared to a fine-grained architecture. Hence, it is expected that coarse-grained architectures become dominant in the HPRC area. Recent FPGAs achieve Teraflops of peak performance due not only to improvements in integrated circuit technology, but also the integration of coarse-grain arithmetic blocks. This may be the way of FPGAs in high-performance computing, that is, devices with both fine and coarse grain floating-point units whose computing datapath can be optimized for the target application. So, the research about high-performance reconfigurable computing architectures is an actual topic of research.

KEY TERMS AND DEFINITIONS

Coarse-Grained Granularity: Refers to the granular size of reconfigurable architectures consisting of arrays of units reconfigurable at the word level. A typical example is an arithmetic unit.

Fine-Grained Granularity: Refers to the granular size of the reconfigurable hardware at the bit level. Fine-grained granularity is typically associated to field-programmable gate arrays.

Granularity: Refers to the relative size of the reconfigurable elements in a reconfigurable hardware architecture.

High-Performance Computing (HPC): Refers to the use of parallel processing techniques to execute computationally demanding algorithms.

High-Performance Reconfigurable Computing (HPRC): A computing paradigm that combines reconfigurable-based processing (e.g., FPGA technology) with general purpose computing systems, whether single general purpose processors or parallel processors.

Reconfigurable Computing (RC): A computing paradigm that uses reconfigurable hardware for computing purposes.

Reconfigurable Hardware: A hardware structure whose logic elements and their interconnections can be reconfigured to implement a particular logic circuit.

Augmented Reality for Tourist Destination Image Formation

Azizul Hassan

Cardiff Metropolitan University, UK

INTRODUCTION

Destination image in recent years is getting hugely interacted with innovative technology application (Lakshmi, & Ganesan, 2010). Tourism is granted as having attachments with destination image when, destination image beholds a significant position. In the simplest understanding, destination image is referred as the expression of an individual's or a group's all imagination, prejudices and objective knowledge about a particular location. In the given context of tourism, this study outlines the roles of AR in destination image formation when, the technology is seen as innovative. This is true that AR has turned into a buzzing word in terms of its uniqueness. AR has already been applied in many areas of human knowledge and business industries creating significant economic and non-economic benefits for both stakeholders and beneficiaries. Still, the benefit generating capacities of AR has not been fully exploited. When, AR and the term 'Gimmick' are almost intertwined, the application of AR in many industries including tourism can hardly be generalised as gimmick. AR does not only serve promotional or marketing activities but also can possibly expanded to destination image formation. This is particularly evident that AR application plays important role in destination image formation (Dadwal & Hassan, 2015). The recent popularity of AR is largely indebted to the technological advancements as wearable or hand-held computing devices and Smartphone. Also on practical ground, Smartphones have played crucial roles for both introducing and popularising AR (Azim & Hassan, 2013).

BACKGROUND

Tourist Destination Image Formation: The exact meaning of tourist destination image is a bit difficult and knotty. So far, this term has been used in diverse perspectives relating destination image. Such image is normally projected by tourism promoters publicly, a destination's stereotype image or individual led destination images. Echtner and Ritchie (1991) noted that, a major part of the definitions of tourist destination image in earlier studies is obsolete. This means that a comprehensive research to define tourist destination image becomes essential. As defined 'image is one of those terms that won't go away ¼ a term with vague and shifting meanings' (Pearce, 1988: 162). Still, the actual meaning of 'image' centres at the core of such complexities. The term has been applied in as considerable number of knowledge disciplines including psychology, behavioural geography and marketing. In psychology, the notion refers to a type of visual representation. In behavioural geography, this turns as more comprehensive as associated with beliefs, values, knowledge, impressions and emotions. However, in marketing, the term points to the attribution underlying image and attach image to consumer behaviour.

One of the accepted definitions of tourist destination image is offered by Crompton (1979:18), 'the sum of beliefs, ideas and impressions that a person has of a destination'. This definition clearly involves individuals when, many other definitions concedes that images can be shared by groups of peoples. From tourism marketing perspective, this is essential to understand the common image facts

with a particular group's other members. Such considerations support market segmentations by facilitating marketing strategy formulations. Another commonly accepted definition of tourist destination image is offered by Lawson and Baud Bovy (1977) as, such image is the outlining of all objective knowledge, imaginations, prejudice, impressions and emotional thoughts that a group of people or an individual can have about a particular destination.

Augmented Reality (AR) and Destination Image Formation: AR technology certainly supports in destination image formation. The technology is viewed as a reliable source for providing necessary photographic and typographic information about a tourist destination (Hassan & Jung, in press). The technology affects tourists' decision by using virtual spaces. A number of platforms as Layar and few others offer the destination marketing organisations (DMO) to publish contents with geo-referencing, tourist attraction descriptions, accommodations, restaurants supported by required information and data about that particular destination (Hassan, 2013). However, such AR technology based contents cannot be widely available to adopt the general users.

Augmented reality (AR) operations rely on computer graphics, computing, sensor and wireless technologies (Hassan & Rahimi, in press). Conventional AR devices as head-mounted displays (HMDs) can be of many types depending on their applications and usability. In a modern GPS supported Smartphone, AR applications can also cover outdoor use. This becomes existent when, tourists normally point the device towards physical objects in a real environment. They are then become able to see the added virtual information on the camera view topped by virtual annotations. The amount and type of contents and information can differ ranging from images, texts, videos or symbols of diverse landmark types.

AR offers benefits to consumers and the tourism society by offering valid destination choice for potential tourists (Hassan & Ramkissoon, in press). This technology allows gathering tourism

industry tailored information to empower tourism consumers. They can then become able to meet certain demands highlighting their preferences and needs (Fritz et al., 2005). The potentials of AR application require proper attention from all concerned parties when, the market potentials become massive. The growing popularity of AR has expanded to move from conventional computing to Smartphone devices. AR as a technology can incorporate with Google AdSense, search engines or even act as a powerful medium of electronic word-of-mouth (Hassan & Donatella, in press; Hassan & Dadwal, in press & Hassan, 2015).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

The aim of this study is to explore AR as an innovative technology application for destination image formation. Also, the study presents some global examples of AR application for destination image formation relating them in the Bangladesh context as an example of emerging tourism economy. The two separate study contexts are the United Kingdom tourism market as pioneering AR application while, the Bangladesh scenario symbolizes a tourism market that readily available to accept an experimental technology.

The sources of travel information as used by the domestic tourists were investigated by Nolan (1976) in this country. The recommendation or advice of friends and family members were found as the most frequent as used as travel information sources. These sources were followed by commercial tourist information and guidebooks and promotional publications. Considering the credibility of the sources of travel information, guidebooks were the highest rated. The government services by the State and suggestions of friends and family members were considered as the most informative. Nolan (1976) also determined the travel information sources' 'objectivity' by inquiring respondents for rating their biasness.

Outcomes as inferred from the results recognised an overall bias in travel brochures as the travel information communication. In the most recent times, communication or recommendations are commonly based on technology when, AR as an innovative technology can have obvious validity.

Solutions and Recommendations

AR and Destination Image in Bangladesh: Bangladesh is a South Asian country having enormous potentials for tourism. The country has enormous tourism resources including the UNESCO World Heritage Sites. A particular tourism destination after enlisted in this list certainly attracts more attention from tourists all over the world (Hassan & Rahman, in press; Hassan & Iankova, 2012). Bangladesh has diverse tourism beauties ranging from naturally to culturally important attractions. The Historic Mosque City of Bagerhat, the Sundarbans and the Ruins of the Buddhist Vihara at Paharpur are some major tourist destinations in the country having the UNESCO WHS accolade. Unfortunately, very limited number of researchers is conducted to explore the manifold touristic approaches of these sites. A series of researches has been conducted to outline manifold aspects of these WHS in Bangladesh facilitating marketing and promotional propensities as: in the study titled, 'Tour on an Imagined Heritage Trail Set in the Mosque City of Bagerhat, Bangladesh: Cogitation for Market Potentials' Hassan (2014a) defines a novel heritage trail in this historic city. Later, he explained its market potentials based on theoretical explanations. Then in the paper titled, 'Package Eco-tour' as Special Interest Tourism Product-Bangladesh Perspective', Hassan (2012a) identifies a relatively new tourism product having a better fit in a delicate and pristine natural setting of the Sundarbans. Also, Rahman and Hassan (in press) critically outline sustainability issues while promoting tourism in the Sundarbans. In addition in the study as titled, 'Macromarketing Perspective in Promoting Tourism: The Case of the Buddhist Vihara at Paharpur' Hassan and Rahman (2015)

suggested the experimental application of macromarketing outlining its affectivity in the given perspective. The country also have untapped medical tourism potentials when, the Algerian scenario also renders some of similarities (Hassan, et al., 2015; Bouziane & Hassan, 2015).

Still, the country does not necessarily have a set of national policies that should benefit tourism (Hassan & Burns, 2014). In tourism, the potential capacities of AR have not been widely exploited. In tourism destinations of Bangladesh, AR is still viewed as remaining at its very infancy stage requiring further development and capacity exploitations. Still, the capacities of destination image formation by AR need to be explored and more researched. These obviously lead to modify the definition of AR in its applied meaning (Olsson et al., 2012). The application of AR technology on Smartphone devices has been naturally adopted by the tourists. However in Bangladesh, the availability of Smartphones is rather limited meaning that the use of AR in this country limits within defined affluent social classes. Still, present status of this specific technology addresses a series of issues to be implemented in a country like Bangladesh having an emerging tourism economy. Tourists' accounts of experiences are important in destination image formation as stated by citing the example of South Korea (Rahman et al., 2013). In Bangladesh, this technology needs to offer pleasant and purposeful tourist experiences.

Innovative marketing approaches are going to lead the future of tourism (Hassan, 2012b; Hassan, 2012c). The incorporation of effective technologies and expert human resources can appear as rewarding in such context (Hassan, 2014b). The impact and effects of AR in destination image formation is significant and expected to get enormous attention in coming years in Bangladesh. However, Bangladesh does not appear to be reluctant to ensure a solid position for this. This means that, AR technology can necessarily attract and motivate tourists to get engaged with a specific tourist destination in Bangladesh. The full

Figure 1. AR for Tourism Destination Image Formation

potentials of AR technology need to be exploited in this country. This should help in destination image formation and benefit the tourism industry very closely and effectively. The effective and proper application of AR should be attached with positive user experience in tourist destination image formation. Over decades, Bangladesh has found non-governmental organisations (NGOs) in development initiatives (Hassan & Ahmed, 2013a). The acceptance of AR for tourism destination image formation becomes important in Bangladesh. An effective use of AR for tourist destination image formation relies on its successful design and implementation. The Bangladesh experiences of non-governmental organisations (NGOs) seemingly appear as a success so far for sustainable development (Hassan & Forhad, 2013b). These positive experiences can suggest including NGOs in the tourism destination image formation supported by AR application. Relying on explanations on potential tourist bases, three basic functionalities of AR are: first, to create interesting image of a tourist destination; second, to form accessible image of a tourist destination and third, to create a playful image of a tourist destination resulting more tourist engagement. The functionalities are as in Figure 1.

FUTURE RESEARCH DIRECTIONS

This is evidenced that, AR is expected to be the key technology in the near future and should be necessarily attended by the tourism industry. Empirical evidences could have better support the arguments made in this research meaning that this was the basic lack of this study. Future researchers can necessarily research on practical user views to outline the concept in clearer and meaningful ways.

CONCLUSION

This study aimed to outline the application of AR as a valid technology to both support and promote destination image formation. The study explores that AR supports in destination image formation. For the academic researchers, this study offers a basic and conceptual underpinning that outlines the potentials and applications of AR technology for destination image formation. This study suggests that the outcome of AR application in tourism destination formation can be positive indicating that the technology can offer good perceived knowledge prior to make a visit. Still

this has also been found that, the application of AR should be based on effective user engagements in a given perspective. Developers and researchers are continuously improving the standards of this technology creating more potentials of AR that has not been exploited. This study establishes that, AR can redefine a tourist destination having interesting, accessible and playfulness images allowing more tourist engagements. In addition, this study offers an overview of AR technology application in tourism destination image formation in an emerging tourism market economy as Bangladesh. In this country, there are opportunities to place this technology into use when, a good destination image can necessarily have positive impacts on tourist's decision making. So, the study proposes to involve innovative technology as AR in destination image formation of countries having emerging tourism economies as Bangladesh. The application of AR is diverse in many areas and particularly in emerging tourism markets as Bangladesh.

KEY TERMS AND DEFINITIONS

Augmented Reality: This technology is regarded as the later stage of Virtual Reality (VR). Following this technology, a human as a user interacts with a computer generated environment that augments reality.

Emerging Tourism Economy: The economy of a country where, the contribution of tourism is getting a gradual importance.

Innovation: Innovation refers to a method, idea, or product that is considered as new.

Internet: Internet is an electronic network connecting billions of computers globally.

Technology Adoption: The adoption or use of a technology.

Tourist Destination Image Formation: Tourist destination is meant as an attitudinal or mental construct development based on impressions.

Tourist Perception: The ideas of a tourist prior to actual visit.

Destination @–Branding of Ten European Capitals Through the Institutional Stems and Commercial Logos

Elena Bocci

Sapienza University of Rome, Italy

Annamaria Silvana de Rosa

Sapienza University of Rome, Italy

Laura Dryjanska

Sapienza University of Rome, Italy

INTRODUCTION

Starting from a broad research programme on *Place-identity and Social Representations of European Capitals in first visitors of six different nationalities* begun by de Rosa in the 1990s (de Rosa, 1995; 1997; 2013b) - later developed along multiple interrelated research lines based on “*field studies*” and “*media studies*”, inspired by a multi-method *modelling approach* to social representations (de Rosa, 2013a; 2013c) - this contribution represents an integrative work concerning a study on the “*Destination@-branding*” (Morrison & Anderson, 2002) of ten European Capitals through communication via their institutional stems and commercial logos.

The research line based on the “*media studies*” (de Rosa, Bocci & Picone, 2012; de Rosa & Bocci, 2014) focuses on the comparative analyses carried out between:

- The “*City@-brand identity*” (Aaker & Joachimsthaler, 2002) created by the marketers (assumed as vehicle of “expert knowledge”) through the institutional tourist websites of ten European Capitals (Rome, London, Paris, Helsinki, Vienna, Warsaw, Berlin, Madrid, Brussels and Lisbon) -examining their usability, interactivity and contents.

- The “*City@-brand image*” (Keller, 1998; Cai, 2002) perceived through spontaneous conversations and experience exchanges among members of the Social Networks, like *Facebook* and *Yahoo Answer* and forum discussions like *TripAdvisor*, assumed as vehicle of the “common sense knowledge”.

In accordance with the model of “*destination branding*” (Cai, 2002) composed by three interrelated components: *brand identity*, *brand image* and *brand element mix* (name, logo, sign, design, symbol, slogan...), this contribution focuses on the institutional stems and commercial logos as symbolic tools and cultural artefacts created in different historical periods in order to contribute to the “*distinctiveness*” of the different cities.

Therefore, the aim is to compare the iconic structural elements of the brands (ancient and modern stems and logos) of ten historical European capitals, which play a determinant role in the narration of urban history.

The research also compares the social representations evoked by brands (stems and logos) of the ten European Capitals among potential first-visitors.

THEORETICAL BACKGROUND

Destination branding constitutes a way to communicate a destination's unique identity by differentiating a destination from its competitors (Morrison & Anderson, 2002).

In the model of destination branding proposed by Cai (2002) -organized around brand identity, brand image and brand element mix- the process starts choosing one or more brand elements -identifying the destination- and goes on with the formation of "brand associations" (attributes, affective and attitudes components of an image -Gartner, 1993; Keller, 1998-) driven by brand identity.

Moving beyond the molecular studies interested in identifying the cognitive and evaluative factors in perception, purely focused on the processes of categorization, encoding, storage and retrieval of information in memory, this chapter captures the multi-dimensionality of the theory

of social representations (Moscovici, 1961/1976; Jodelet, 1989; de Rosa, 2013a, 2016).

MAIN FOCUS: THE BRANDS

Modelling Approach Research Design

Given the relevance assigned to the iconic-imaginary dimension to social representations by the "modelling approach", the brands have been studied by using an appropriate research design as described in the Figure 1.

The "*modelling approach*", developed by de Rosa (2013a, 2014) is a paradigmatic option specific to the research field inspired by the Social Representation theory. It is aimed to grasp its core value as a unifying meta-theory of the social sciences, by operationalizing the investigation about any object of this supra-disciplinary field

Figure 1.

Table 1. The main features of the research design

Objective	Methodology	Questions	Hypotheses	Main results
The aim is to compare the iconic structural elements of the brands (ancient stems and modern logos) of ten historical European capitals, which play a determinant role in the narration of urban history.	In order to identify the social representations of the brands (stems and logos) we used: 1) a grid has been created ad hoc to identify the structural (distinctive) elements of the brands. (structured tool)	1) Which are the structural elements of the stems and logos?	We expect to identify discrepancies and/or contrasts of meaning between institutional stems and commercial logos in terms of structure of the elements that characterize these brands since, even though both are aimed at distinctiveness and recognition: • stems have historic roots, which often date back to the origins of the city; • logos were created in modern times, for well defined marketing purposes.	The stems origins from heraldry and evoke the prestige of the cities through rich combinations of different kind of elements: royal, military, religious or symbolic/mythological and natural. In many cases the history of the city contains elements of legends or religious beliefs, often recalling virtues of the Saints. These elements, present in the stems, narrate the history since the cities' foundation. On the commercial logos complex figures disappear completely, leaving space to modern elements: essential lines, abstract signs and circles innovating the brand and referring to socio-recreational, emotional, architectural and design aspects. These logos aim "to sell the city product", starting from the assumption that places can be branded just like products to maximize their attractiveness and their enjoyment by visitors.
The research compares the social representations evoked by brands (stems and logos) of the ten European Capitals among potential first-visitors.	2) the "associative network" using as iconic stimuli both the stems and the logos of each of the ten Capitals, able to determine the structure, contents and polarity of the Social Representations of stems and logos (de Rosa, 2002, 2003, 2005) (projective tool)	2) Which are the main differences between the social representations evoked by stems and logos? (Strengths and weaknesses; attitudes etc.) 3. Concerning commercial logos, is it possible to improve them and how?	We expect to identify discrepancies and/or contrasts of meaning between institutional stems and commercial logos concerning attitudinal components of their social representations since, even though both are aimed at distinctiveness and recognition: • stems have historic roots, which often date back to the origins of the city; • logos were created in modern times, for well defined marketing purposes. • We expect that it is possible to improve some logos by taking into account social representations of the cities.	Referring to the evaluative component of the social representations, the calculation of the indexes of polarities allowed us to detect a general more negative attitude towards institutional stems than towards commercial logos. In particular, the stems with the lower index of polarity are those of Berlin and Warsaw, while the institutional stem of Lisbon is the only case where the institutional stem has a more positive evaluation than the commercial logo. The reason has been found in the contents of the different brands: the richness of details -that take us back in time to the colonialism- and the predominance of yellow are the strengths of the stem; while, having taken over the central part of the emblem, using only the black colour and clean lines constitute leads to more negative evaluation of the commercial logo. It is possible to improve some logos. i.e. while the commercial logo of Rome is not among the best ones in terms of approval rating, the idea of an increased focus on a city with which one can co-establish a communication able to evoke a more intimate relational dimension should reinforce -with a positive effect- the trend already registered for brands like Paris. To embody the emotional-relational dimension seems right also for other capitals, such as Helsinki, London and Vienna.

Figure 2.

in multi-methodological research designs. These require to be fully justified and adequately complex depending on the multi-theoretical perspective adopted and the variety of constructs selected (representations, identity, social memory, emotions, etc.) the diverse techniques of data collection (structured and projective, textual and figurative, verbal or behavioural, etc.) the choice of the data analysis strategies and the expected results.

Research Focus

In this contribution the following brands (institutional stems and commercial logos) have been considered:

Research Instruments and Data Analysis Strategies

Structural and projective techniques have been created or developed, considering as iconic stimuli both the stems and the logos of the ten Capitals.

1. The grid is a structured tool, in format of a table, realized ad hoc for this research line and aimed to detect the presence/absence of the following distinctive components of the brands:
 - a. Name of the capital and texts in national languages;
 - b. Slogan;
 - c. Acronyms and texts in Latin language
 - d. Royal elements;
 - e. Elements of military origin;
 - f. Religious or symbolic/mythological elements;
 - g. Natural elements;
 - h. Abstract graphic elements.

The grid has been applied to all the stems and logos in order to identify the structural main elements of the different brands.

2. The “associative network” (de Rosa, 2002; 2003) is a tool of a projective nature; there-

Figure 3.

fore it is less subject to the phenomenon of social desirability, if compared to structured tools like for example a questionnaire. It enables respondents to specify the structure, content and polarity of a semantic field by themselves.

The tool requires first to associate words with stimulus and then to establish connections and branching patterns between the elicited words that are written around the brand.

The associative network requires people to attribute a particular polarity to each word (positive, negative or neutral) to describe its connotations. This allows to detect the evaluative component of the representations. A polarity index calculates the positive, negative, or neutral connotations of the free associations evoked by each of the iconic stimulus used in this study. This index, which varies from +1 to -1 is calculated using the following formula:

Polarity Index (P) = (n° of positive words – n° of negative words)/total n° of associated words.

A second “neutrality” control index, which also varies between -1 and +1, is also calculated.

Neutrality Index (N) = (n° of neutral words – (n° of positive words + n° of negative words))/total n° of associated words.

Sample iconic stimulus are presented in Figure 3.

Through the software SPAD (Lebart, Morineau & Beque, 1989) applied to the associative network, it is possible to reconstruct the structure and content of the representational fields associated with the iconic stimuli (procedures

Talex-contingency tables- and *Corbit*-analysis of latent dimensions, including as active variables indexes and words evoked-).

For each of the iconic stimuli the first five factors were extracted, whose cumulative percentage of variance explained more than 80% of the total.

Among the indicators useful in the interpretation of the results, the following are taken into account:

1. The factorial coordinates of each word on the first 5 factors which establish their position in the axes, in terms of distance from the origin and positioning on the positive or negative side;
2. The absolute contribution, which constitutes the part of the total inertia of the factor explained by each variable (Ercolani, Areni & Mannetti, 1990);
3. The relative contribution, or cosine squared, which assesses the contribution the factor provides to the explanation of the variability of each modality.

The analysis makes it possible to identify hidden dimensions (factors) that are subtended to the data and summarize the relations between original variables.

The aim is that of rendering of simpler interpretation the whole range of information through a synthesis, so that newly identified factors could represent a good approximation of the starting data-matrix. Due to limited space, this chapter takes into account the factorial interpretation, leaving out further elaborations of geometric-structural nature.

Destination @-Branding of Ten European Capitals

Table 1. Elements of congruence/difference between the brands of the various capitals under scrutiny

Brands	Institutional stems		Commercial logos	
Name of the capitals and texts in national languages	Absent		BERLIN BRUSSELS HELSINKI LISBON LONDON MADRID PARIS ROME VIENNA WARSAW 	
Slogan	Absent		VIENNA  WARSAW 	
Acronyms and texts in Latin language	LONDON  Domine Dirige Nos PARIS  Fluctuat nec mergitur ROME  S.P.Q.R.		Absent	
Royal elements (wreaths and crosses)			Absent	
Elements of military origin	LONDON  helmet and shield PARIS  medals WARSAW  shield and sword BRUSSELS  Shield		Absent	

Brands	Institutional stems		Commercial logos		Brands	
Religious or symbolic/ mythological elements	LONDON  winged dragon WARSAW  mermaid BRUSSELS  golden lions with red tongues		WARSAW  mermaid -also abstract graphic elements-		ROME  wolf and Traian's column	
Natural elements	LONDON  oak leaves BELGIUM  waves of the white sea PARIS  laurel wreath BERLIN  bear MADRID  bear and fruit tree LONDON  sea and black crows BRUSSELS  lawn ROME  Eagle		LONDON  river -also abstract graphic elements-		LISBOA  sea and black crows BRUSSELS  iris	
Abstract graphic elements	Absent		HELSINKI  the image of H consists of 7 circles metaphors of: 1) bridge between West and East; 2) the archipelago and the Baltic Sea; 3) a metropolis of a friendly size; 4) environmental concern and safety; 5) activism and culture; 6) architecture and design; 7) agreeable people.		PARIS  Eiffel Tower BERLIN  Brandenburg Gate	

The analysis was carried out on a group of 40 potential first visitors, experts in training in “Marketing and Communication” (Master level) at

the Faculty of Medicine and Psychology - University of Rome “La Sapienza”. They have followed the Laboratory of Web Marketing, focusing the

analysis of Social Representations of Historical Capital Cities.

Results of the Analysis Through the Grid

The analysis of the brands, made using the *ad hoc* designed grid, highlighted differences between stems and logos under scrutiny (Table 1).

The table allows us to answer to the following main question:

Question 1: Which are the structural elements of the stems and logos?

The stems origins from heraldry and evoke the prestige of the cities through rich combinations of different kind of elements: royal, military, religious or symbolic/mythological and natural. In many cases the history of the city contains elements of legends or religious beliefs, often recalling virtues of the Saints:

- The “armed mermaid” recalls a mythological figure prepared to protect the city of Warsaw and its inhabitants;

- The “dragons” refer to Saint George’s victory over one of them depicted in the stem of London;
- The “crows” in the stem of Lisbon lift up in the air the body of Saint Vincent, then recovered by his followers;
- The “burgundy color” of Rome recalls the legend of Ancile, one of twelve sacred shields kept in the Temple of Mars, which fell from heaven during the reign of Numa Pompilius to protect the city;
- The “Archangel Michael” pierces the black devil in the stem of Brussels.

These elements present in the stems narrate the history since the cities’ foundation. On the commercial logos complex figures disappear completely, leaving space to modern elements: essential lines, abstract signs and circles innovating the brand and referring to socio-recreational, emotional, architectural and design aspects. These logos aim “to sell the city product”, starting from the assumption that places can be branded just like products to maximize their attractiveness and their enjoyment by visitors (Ashworth, 1994; Anholt, 2003, 2010; Freire 2005), as summed up in Figure 4.

Figure 4.

Results of the Analysis Through the Associative Networks

The following figure helps us to answer the main question:

Question 2: Which are the main differences about the social representations evoked by stems and logos? (Strengths and weaknesses; attitudes etc.)

The figure compares the average polarity indexes calculated from the positive, negative and neutral assessments attributed by research participants to the associations evoked by the stems and logos of the ten historic European capitals.

First, the cases where the average polarity index of the representational field evoked by institutional stems is lower shall be examined. *Which social representations are evoked by these stems?*

In both cases the overwhelmingly important topic is the “war”.

Concerning the city of *Berlin* (average index of polarity institutional stem 0,040), next to the functional aspects of a city considered as “organized” (first factor, positive semi-axis, a.c.3.6 r.c.0.49) appears the historic-artistic-cultural dimension with terms such as “wall” (a.c.7.9 c.r. 0.78) and “museums” (a.c.3.1 r.c.0.29) on the negative semi-axis of the first factor; “Brandenburg Gate” (a.c.6.2 r.c.0.43) and “culture” (a.c.5.2 r.c.0.40) on the positive semi-axis of the second factor; the tight relationship of art/culture with the darkest period of recent history tends to be associated with a negative polarity index on the two factors

(negative semi-axis of the first factor a.c.11.8 r.c.0.26; positive semi-axis of the second factor a.c.11.9 r.c.0.16).

The binominal art/culture and the history of the XXth century can be seen even clearer in the social representations of stems, as demonstrated in the first two factors: the first factor–negative semi-axis- includes such terms as: “nazism” (a.c.17.8 r.c.0.89), “East Berlin” (a.c.11.1 r.c.0.68), “war” (a.c.10.3 r.c.0.88) and “wall” (a.c.5.1 r.c.0.37) and the second factor – negative semi-axis- includes such terms as: “wall” (a.c.8.7 r.c.0.50) and “violence” (a.c.4.1 r.c.0.30). In both factors active variables elicited coincide with a negative polarity index (negative semi-axis of the first factor a.c.14.2 r.c.0.33; negative semi-axis of the second factor a.c.11.2 r.c.0.51).

It is the second factor in particular that shows a split in the attitudinal component of social representations; while the negative polarity goes with the historical events of the last century, the positive polarity corresponds to recent cultural events (“Cinema Festival” a.c.10.2 r.c.0.60) and to ancient history of the city (“ancient” a.c.4.2 r.c.0.37).

References to the XXth century for the city of Berlin are in continuity with the city of Warsaw (average index of polarity institutional stem 0.1393) whose brands are full of events related to World War II. In reference to the commercial logo, the word “Auschwitz” occurs on the second factor of the positive semi-axis (a.c.15.2 r.c.0.53) next to “cold” (a.c.26.6 r.c.0.78) and “sad” (a.c.11.4 r.c.0.86) associated with a negative polarity index (a.c.70.6 r.c.0.96); on the positive semi-axis of the fourth factor (a.c.10.1 r.c.0.14), as well as on the negative semi-axis of the fifth factor (a.c.21.6 r.c.0.22).

The history of the XXth century also shows an impact in the social representations evoked by the stems.

The first factor in particular demonstrates a rift in the attitudinal component of social representations:

Figure 5.

- On the positive semi-axis the positive polarity (a.c.26.8 r.c.0.79) corresponds to general aspects such as “history” (a.c.5.4 r.c.0.29) and nature-related themes (“river” a.c.7.1 r.c.0.60);
- On the negative semi-axis negative polarity (a.c.43.1 r.c.0.83) corresponds to the references to the “difficult” (a.c.7.5 r.c.0.65) period of the Second World War that caused suffering and victims, with terms like “blood” (a.c.14.4 r.c.0.68) and “war” (a.c.10.6 r.c.0.63).

The word “Auschwitz” appears on the positive semi-axis of the second factor (a.c.45.9 r.c.0.73), together with “Poland” (a.c.19.0 r.c.0.82) and “antique” (a.c.14.3 r.c.0.40), contaminating time and space, and on the positive semi-axis of the third factor (a.c.11.5 r.c.0.14) together with “war” (a.c.6.4 r.c.0.23).

Next, the city of *Lisbon* (average index of polarity institutional stem 0.5135) is examined; the only case where the stem has a more positive evaluation than the logo.

What are the strengths of the institutional stem and what are the weaknesses of the commercial logo?

The richness of details -that take us back in time to the colonialism- and the predominance of yellow are the strengths of the stem; while, having taken over the central part of the emblem, using only the black colour and clean lines constitute leads to more negative evaluation of the commercial logo.

In spite of common elements:

- For the stem the positive social representations coincide with the references to “colonialism” presented on different factors: negative semi-axis of the third factor with keywords such as “wealth” (a.c.6.5 r.c.0.32), “history” (a.c.6.1 r.c.0.66), “power” (a.c.5.4 r.c.0.43) and “sea” (a.c.3.1 r.c.0.24); positive semi-axis of the fourth factor with the keywords “Middle Ages” (a.c.6.3 r.c.0.19)

and “boat” (a.c.7.3 r.c.0.37) and also on the negative semi-axis where are present “colonies” (a.c.9.1 r.c.0.39), “riches” (a.c.7.0 r.c.0.32), “trade” (a.c.6.0 r.c.0.37) and “discovery” (a.c.4.2 r.c.0.45); positive semi-axis of the fifth factor with the words “colonies” (a.c.11.7 r.c.0.34), “trade” (a.c.6.0 r.c.0.25), “discovery” (a.c.5.1 r.c.0.37), “boat” (a.c.4.8 r.c.0.16);

- For the logo the negative polarity index corresponds to the positive semi-axis of the second factor (a.c.46.2 r.c.0.72) and to the negative semi-axis of the third factor (a.c.8.5 r.c.0.9) to the negative emotion “sadness” (respectively a.c.34.1 r.c.0.73 on the second factor and a.c.6.1 r.c.0.9 on the third factor), also associated with the “black” colour on the second factor (a.c.12.5 r.c.0.47).

In the following section we present the analysis of the cases where the positive polarity index of the commercial logos are higher:

Which social representations are evoked by these logos?

Social representations associated with the logo of *Brussels* (average index of polarity for commercial logo 0.6855), rich in metaphors, are centered on the topic of “multi-culturalism”. Sometimes interpreted as a “bar code” (first factor negative semi-axis a.c.54.1 r.c.0.91; second factor negative semi-axis a.c.8.2 r.c.0.6), the colors bring to mind the idea of a “game” (first factor negative semi-axis a.c.24.1 r.c.0.56), in other cases they are a synonym of the “rainbow” of races-cultures (third factor positive semi-axis a.c.5.5 r.c.0.43; fifth factor negative semi-axis a.c.5.5 r.c.0.20), an invitation to “open up” (third factor positive semi-axis a.c.8.0 r.c.0.42) and to “love” (a.c.5.2 r.c.0.19). Love appears both on the positive semi-axis of the third factor and fourth factor (a.c.4.5 r.c.0.13), here also together with “multicultural” (a.c.3.2 r.c.0.21).

The content associated with the institutional stem of *Brussels* appears very different from the

one evoked by the commercial logo, concentrating on the historical/cultural and religious elements evoked by the legendary mythological figures represented.

After Brussels, also the commercial logos of Madrid and Paris are very positive. The positivity seems related to “nightlife” that cuts across different factors, referring to socio-recreational city through more keywords: the “night life” appears on the negative semi-axis of the second factor (a.c.6,8 r.c.0.46), together with “inviting” (a.c.5.5 r.c.0.39) and on the positive semi-axis of the fifth factor (a.c.6.2 r.c.0.25), together with “happiness” (a.c.14.7 r.c.0.63), “sea” (a.c.13.7 r.c.0.59) and “youth” (a.c.4.9 r.c.0.76); on the positive semi-axis of the third factor there is “movida” (a.c.3.3 r.c.0.20), together with the “sun” (a.c.4.9 r.c.0.66), “sea” (a.c.3.8 r.c.0.20) and “heat” (a.c.3.5 r.c.0.12).

Free associations related to the institutional stem of Madrid do not seem to refer to the characteristic “movida” (nightlife), remaining somewhat of a descriptive/evaluative dimension of the elements represented.

Also for Paris, as in case of Madrid, the relational dimension is enhanced in the commercial logo from a more intimate perspective, which leaves room for romance, as we can observe in the third factor extracted from Spad. On the positive semi-axis appear in fact words like “charming” (a.c.16.4 r.c.0.65), “romantic” (a.c.8.7 r.c.0.63), “magic” (a.c.7.3 r.c.0.56), “evening” (a.c.4.7 r.c.0.29), “lights” (a.c.3.2 r.c.0.11); on the negative semi-axis of the same factor the dimension of values is expressed through such terms as “love” (a.c.13.0 r.c.0.72) and “Christmas” (a.c.4.8 r.c.0.28). “Christmas” (a.c.20.0 r.c.0.48), “fascinating” (a.c.9.7 r.c.0.16) and “romantic” (a.c.3.5 r.c.0.11) is also repeated on the positive semi-axis of the fifth factor.

The relational/value dimension is also detected in reference to the institutional stem; on the first, second, fourth and fifth factor recur the words “light” and “romantic”, also repeated on the positive semi-axis of the second factor in correspondence with the word “love” (“lights”

a.c.5.4 r.c.0.26; “romantic” a.c.5.4 r.c.0.26; “love” a.c.4.3 r.c.0.51).

FURTHER RESULTS AND RECOMMENDATIONS

Recently “Roma Capitale” has modified her brand, from the old stem to and the old logo both with historical iconic (“crown”, “shield”, “wolf”) and textual symbols (“S.P.Q.R.”, “capital”) to the new one including a strong “relational” attachment and identification dimension (Rome & You)¹.

According to our results, while the commercial logo of Rome is not among the best ones in terms of approval rating registered by the polarity index, the idea of an increased focus on a city with which one can co-establish a communication that is not pre-defined and able to evoke a more intimate relational dimension should reinforce -with a positive effect- the trend already registered for the analyzed brand (similar to that of Paris, with keywords as “lights”, “romantic” and “love”).

To embody the emotional-relational dimension seems right also for other capitals, such as Helsinki, London and Vienna. In fact, despite that one of the seven points of the commercial logo of Helsinki refers to the friendliness of people, in the eyes of research participants the relational component is absent in the five factors extracted for each of the three capitals –for both brands-; moreover, concerning the emotional dimension

Figure 6.

Figure 7.

appears only the word “sad” (a.c.26.4 r.c.0.63) -for commercial logo- precisely referring to Helsinki, on the negative semi-axis of the third factor, together “communication” (a.c.6.5 r.c.0.83) and “modern” (a.c.4.7 r.c.0.53), marked by a negative polarity index (a.c.43.3 r.c.0.58).

In proposing recommendations, however, it should be noted that these changes often become the subject of a polemical social discourse that is increasingly divided over the Internet (especially websites, blogs and social networks) and can even last for years, as was the case for commercial logos used in this research related to London² and Rome³ or more recently during the presentation of the new logo that generated strong protests and complaints⁴:

The controversies triggered by the web show that: touching iconic symbols generates more controversies than replacing words, as de Rosa learned investigating the controversial representations provoked by the change of the logo of the Italian Communist Party (P.C.I.) (de Rosa & Farr, 2001; de Rosa, 2014).

The symbols seem to possess the power of materialising the deepest dimension of the figurative nucleus of the social representation. More specifically, some of the elements that can be included

under the label “brand element mix” possess, as Rouquette noted (1994), the following properties:

- They embody the emotive dimension of the central nucleus of a social representation -dimension defined by the author with the term “nexus”-;
- Merge denotation and connotation;
- Reify (objectify) a system of cadences and values;
- Are hard to modify through analysis and rational reflection;
- Constitute a system of communication relatively independent vis-à-vis that of the discourse. (...)

In the symbolic order, in fact, to act on the symbol of a person or of an object, means to act on the person or on the object itself. To strike the symbol means to strike directly the entity that it represents (de Rosa & Farr, 2001; de Rosa, 2014).

FUTURE RESEARCH DIRECTIONS

Given the continuous evolution of some of the commercial logos, like the logo of Rome discussed

above, the future research should include these new logos and compare them with the previous ones. Moreover, the results obtained by analyzing the institutional and commercial logos as elements of the “brand element mix” should be further integrated with those concerning the divergence/convergence of the City@-brand identity and City@-brand image, for a comprehensive view of the Destination@-branding of the ten European Capitals.

CONCLUSION

Following our hypotheses, the main differences between stems and logos emerged through the use of the ad hoc grid that showed the divergences in the structural elements of stems and brands and also through the calculation of the indexes of polarities that allowed us to detect a more positive attitude towards commercial logos than towards institutional stems.

On the contrary, shared contents between stems and logos have been found referring to:

- The “history” - the “Second World War” in the brands of Berlin and Warsaw and the “colonialism” in the brand of Lisbon -;
- The “emotional” and “value-related” dimensions in the brands of the romantic Paris and Rome.

Concerning commercial logos, especially the “emotional” and “value-related” dimensions affected in the opposite way (negative vs positive) the social representations:

- Negatively in the cases of Warsaw and Lisbon (sadness);
- Positively in the cases of Brussels, Paris and Rome (love) or Madrid (happiness).

Following the improved importance of the “emotional” and “value-related” dimensions (Preiti, 2013) the recent idea of a new commercial

brand for Rome - including a strong relational dimension - is in line with the communicative policies adopted by other capitals. The polemical social discourse that it has activated among citizens confirms the dynamic of resistance/acceptance in the social representations provoked by changes related to their symbolic and iconic dimensions and the interest for investigating the social and communicative phenomena related to the iconic narratives about cities evoked by the brands and the city destination@-branding” (Bocci, de Rosa, & Dryjanska, 2015).

Besides their descriptive value and possible function in guiding city’s institutional and tourist communication managers, the results have a historical value with respect to the evolution of the Institutional communication, assuming a particular interest for further comparative analyses (de Rosa & Bocci, 2013; de Rosa, Bocci & Picone, 2012) concerning the specific component of the brand element mix (Cai, 2002), here analytically described through structured and projective tools aimed at identifying both the structural (distinctive elements) of the brands and the structure, contents and polarities of the social representations associated to them.

The study is part of a more general attempt to deal with the complexity of the new communicative web scenario based on multi-channels, assumed to be influential for the genesis, transmission and negotiation of the social representations of historical Capital Cities. The policy makers should therefore take into account social representations and test innovative design ideas in order to verify that a new logo for example includes elements considered as essential in how people represent a city.

KEY TERMS AND DEFINITIONS

Associative Network Technique: A tool developed by Annamaria Silvana de Rosa of projective nature used in order to study the Social

representations of iconic and verbal stimuli, by considering structure, contents and attitudes.

Destination@-Branding: Extension of the concept of destination-branding to the digital world of the Internet, including websites, social networks, portals, etc.

Destination-Branding: An articulation of different interrelated components: brand identity, brand image and brand element mix.

Index of Polarity: An index created by Annamaria Silvana de Rosa aimed at detecting the evaluative component of social representations, on the basis of the polarities (positive/negative) attributed to the words associated by the subjects to the stimuli.

Modelling Approach: A paradigmatic approach to Social Representations developed by Annamaria Silvana de Rosa that integrates different methods and techniques coherently with the articulation of different theoretical constructs and dimensions.

Nexus: The emotive dimension of the central nucleus of the social representations.

Social Representations: Naïve theories of common sense that express systems of values, convictions and norms of behavior, with a double function of organizing the perception of the world and serving as a shared system of social communication and interpersonal exchange.

The Effect of Social Media Networking in the Travel Industry

Androniki Kavoura

Technological Educational Institute of Athens, Greece

Efstathios Kefallonitis

State University of New York at Oswego, USA

INTRODUCTION

Many travelers have at least one account in one of the popular social media networking websites or applications (Facebook, Twitter, Flickr, Instagram). Airlines and travel agencies often encourage their customers to use their personal profile to: (a) either interact with the company directly and (b) participate in online discussions with other users about that company. The use of social-media for the purpose of interacting with travel industry companies and other travelers has created multiple online communities. The travel industry is using these online communities as a new advertising and communication channel to reach customers, thus serving both as a customer service and innovative marketing tool.

The multidisciplinary nature of this chapter identifies under-researched areas and sheds new light in the way that connected passengers search for travel-related information. The authors aim in exploring ways that connected passengers develop a sense of belonging in social-media networking websites.

The use of new technologies and new methods of communications in the travel industry has reinforced the need for dialogue among providers (airlines, travel agencies and so on) and users (passengers). Online communities serve as a networking platform that brings together positive and negative comments.

BACKGROUND OF RESEARCH: DEFINING SOCIAL MEDIA

Social media are Internet tools where people interact by creating user-generated content. This is an asynchronous channel of communication. There is perceived interactivity since interaction may not be necessary nor interpersonal. Communication may take place either via web-based technology or via mobile device applications (Carr & Hayes, 2015). Facebook users post comments and like other people's posts in order to communicate. In addition, Facebook users play online games, share personal experiences and interact by following other people's updates. This makes users feel a sense of belonging by sharing moments and keeping in touch with friends and relatives.

Flickr is a 'photo sharing community'. It consists of a user-generated online social network where users tell stories or share moments using photographs. The personal perspective of the user gets shared with the entire Internet community. This photo-sharing creates experiences that can be understood by larger groups of people (Dotan & Zaphiris, 2010). Photographs are used as a form of a visual vocabulary used along with hashtags. These are user-generated metadata, which organize the uploaded photos using hashtag as a means of coding. On Flickr a relationship exists between social affiliation (contacts) and hashtag vocabulary formation (Dotan & Zaphiris, 2010).

According to the Annual Report of Facebook, the global advertising revenue in 2015 is expected to reach 14.27 billion US dollars (“Facebook’s Advertising Revenue”, 2015). This demonstrates the tremendous advertising growth and a great opportunity. An increasing number of people spend more time online and less time using other digital media. The greater use of social media networks as part of marketing communications has the potential to outnumber traditional channels (Hutter, Hautz, Severin Dennhardt, & Füller, 2013). The success of social media marketing lays on the interactivity of the medium. This offers interaction among users and companies with the scope of increasing a company’s brand awareness.

There has been little research on the importance of interactivity between companies and consumers using new technologies. In particular ways that firms can communicate with their customers, learn from feedback received and engage with users in an interactive way.

THE ROLE OF CULTURE IN THE IMPLEMENTATION OF SOCIAL MEDIA USAGE

Social sensitivities need to be taken into consideration when online social networks and online communities are created. Customs, social norms and traditions sometimes dictate what is socially acceptable or not in an online community. Community is best understood as a sense of (or belief in) group commonality. Online communities are products of culture and reflect certain practices or acts exercised within that culture. Examples include ways of naming a community. Hofstede (1980) argued that culture influences a human group’s response to its environment. Culture may determine dominant issues within a community.

An example of cultural interference comes from the People’s Republic of China, where Facebook, one of the most popular social network websites, is currently banned (Riley, 2015). This is only accessible in Hong Kong (SAR). On the contrary,

local social networking websites such as renren.com are rather popular. Japan’s most popular social network website mixi is accessible to Japanese citizens with more than 27.1 million users. Mixi users are estimated to be approximately 5 million back in 2006, while Facebook users today are about 15 million (“About Mixi”, 2015; Ghedin, 2013).

In order for marketers to create strong online brand communities, they need to create or adopt a language or symbols that will help them connect better to their respective communities. This language will have to take into consideration cultural issues and sensitivities. Further research is needed to examine the significance attributed to the concept of a constructed language, along with its symbolism. Preliminary exploratory research in the hotel and tourism industry illustrated that members of an online community prefer using code-words, symbols and a commonly understood language (Kavoura & Tiago, 2016). Further research in this field will provide further insights.

ONLINE COMMUNITIES: PASSENGERS AND THE TRAVEL INDUSTRY

Users attracted to social networking websites have a certain degree of homogeneity. Usually they speak the same language and share similar interests in order to be incorporated in the social networking group. Gregorie, Salle, & Tripp (2015) pointed out that emphasis should be placed on the connected passenger and the respective online communities he/she belongs. Social media are changing the traditional communication norms between the customer and the company and user-generated content can in fact influence a company’s reputation.

The user-generated content of all users is available to the entire social media platform. This may influence others, meet popularity and create trends. Content creators often act as ambassadors of ideas or may represent a company and its products. Content creators are members of the

public or even well-known entities such as actors and athletes and so on. There are businesses that send posts to first-time users; recipients of these notes often post them on social media, increasing the brand's exposure (Lee, 2013). Research on the use of Facebook by airports, shows that the most influential posts are those that engage users and encourage online comments (Wattanacharoensil & Schuckert, 2015). User-generated communities on social media are generally more trusted than the corporate websites or blogs created by travel-related providers (Del Chiappa, 2013; Amaral, Tiago, & Tiago, 2014). This reveals that social-media users do not always trust the information that companies decide to share publicly. There have been cases that incidents of dissatisfied customers go viral on social-media platforms. Such an example was the case of a passenger's broken guitar when he flew United Airlines. The passenger created a YouTube video that attracted more than 15,343,972 views ("United Breaks Guitars", 2009).

Large amounts of useful data can be collected based on customers' points of view who act as co-creators in the marketing but also in the research and development process of the firm (Harrigan, Soutar, Choudhury, & Lowe, 2015). In fact, customers become the co-creators and companies can enhance their experiences by listening to their point of view (Prahanland & Ramaswamy, 2013). Thus, social media can be used as a means of enhancing Customer Relationship Management (CRM). Social media offers a platform to engage with the public on multiple levels and serves as a useful customer preference database (Harrigan et al., 2015).

Gunarathne, Huaxia, & Seidmann (2015) argue that firms and airlines are willing to respond to customers' comments and provide customer support in real time basis via the use of social media. An interesting finding reveals that some airlines give priority to customers with a higher number of online followers. A tool that helps marketers evaluate the social networking comments is reputation monitoring (Ntalianis, Kavoura, Tomaras,

& Drigas, 2015), besides websites such as Brand Watch, Hootsuite and others (Harrigan et al., 2015). Airlines can monitor the comments made with regard to their products and act accordingly.

Social media create online communities in the sense that online communication is used in a virtual environment that connects all those with similar interests (Sakas, Nasiopoulos & Kavoura, 2015). An airline may use social media to engage those customers who use social media intensely since a correlation has been found to exist based on research of an international airline; this in turn, may be used for the benefit of the airline's reputation (Dijkmans, Kerkhof, & Beukeboom, 2015). There are a number of different ways to complete travel reservations online. These include the use of online travel agents or airline websites. Both use a variety of ways to make their services accessible to the consumer such as websites, mobile applications, self-service kiosks and so on. This elevated experience and the variety of choice available are factors that influence consumer preference and choice (Holland, Jacobs, & Klein, 2015; Ntalianis et al., 2015; Xiang, Magnini, & Fesenmaier, 2015).

Reposting information on a variety of social media that feeds off from one single source is also a valid way to generate a unified voice and have presence in a variety of social media networks (Kroque, 2013).

Firms may invest a lot of money to attract customer engagement and promote a brand's name with the use of contests and competitions, (see for example, JetBlue's Airways contest in Sakas et al., 2015). Engaging the user is another way of communication that demonstrates care by answering questions, providing advice but also sharing life experiences online (Palsule, 2011; Kosarek, 2014). Such actions present a fine way of online interactivity by engaging in users' everyday lives. Twitter uses such an engagement in order to measure the number of retweets, responses and mentions. This allows an advertiser to have greater control over the budget and the outcome (Bershidsky, 2013).

Twitter engages users by employing replies and mentions. This is intended to make communication between users easier (“How to”, 2015). JetBlue Airways has almost 1.800.000 followers on Twitter (“JetBlue”, 2015a) and uses a personalized way to get in touch with users, aiming at specific people and offering a personal touch. It is typical that JetBlue Airways refers to the names of their customers on their personalized communication. As an example: “We’re lucky to have you as a customer [name of the customer]! As you know, we always welcome you on board with open arms! See you soon!” (“JetBlue”, 2015b).

Elaborating on stories is another practice that may bring a community together. Video clips that show the company’s interest in making a customer happy are increasing in popularity. Another example associated with the airline industry, was a marriage proposal that became viral. A JetBlue passenger wanted to propose to his girlfriend in-flight and the screens on the airplane loaded the video he had prepared (“Adam and Taryn”, 2013). It is not the narrative that is of significance but rather a story with a thematic development (van Dijck, 2013).

Overall, there are a number of opportunities regarding the use of social media in the travel industry:

Opportunities:

1. To create a unique personality and seamless experience for a traveler. This can be utilized best by using a variety of social media platforms such as Twitter, Instagram, Facebook etc.
2. To reach a wider range of users, since some travelers may show preference to one social media platform than another.
3. To maximize the impact of their social media by driving traffic to their main corporate site.

What can make or break a social media campaign is the way that engages the public and the response rate to customer posts.

THE CONNECTED PASSENGER, SOCIAL MEDIA APPLICATIONS AND CHALLENGES OF THE TRAVEL INDUSTRY

The connected passenger is a traveler that reads and interacts on user-generated websites and other web-based applications in order to find travel-related information regarding flights, hotels and so on. The development and growth of online communities has affected the modern-day traveler (Samson, Mehta, & Chandani, 2014). Online communities continue to develop a rather extensive wealth of travel-related information, such as reviews and provide advice for fellow travelers (TripAdvisor, Yahoo Travel, Seatguru).

Connected passengers use information from user-generated websites to:

1. Acquire current travel-related information from other travelers rather than rely on the material that the respective businesses decide to make public. Travel-related information may refer to airline services, hotel amenities, specialty restaurants.
2. Connect online with other travelers. This often generates code words that may form a language. This is common among online communities.

Modern-day passengers do not passively observe what the travel industry providers chose to present (Pang, Begam Binte Abul Hassan, & Chee Yang Chong, 2014). They would rather search for information themselves and try to verify details before completing an actual travel purchase. Passengers like to be aware of what is happening behind the scenes of a travel services provider, particularly what is willingly made public and whether companies are true to their promises. The online communities available on social media offer a platform to share such information among travellers (Bernabé-Moreno, Tejeda-Lorente, Porcel, Fujita, & Herrera-Viedma, 2015).

Figure 1. Schematic perception of airline communication challenges

Travellers show resistance to mass-produced products. The connected traveller shows preference to custom-made tailored options based on his/her needs (Kefallonitis & Sackett, 2004). Tailor-made travel options give travellers the feel of being special; a feeling that some consumers desire. Passengers look for uniqueness and are motivated to purchase offerings that will offer them this unique, special feeling (Rajović, & Bulatović, 2014).

Travel-related services begin and end with people. It is a transitional process from human to human (Perry, Damian, & Lagu, 2014). Taking an airline example: All members of crew, ranging from ground to flight-crew employees personify the brand image of the airline. The overall behaviour of the employees becomes part of the airline brand. The airlines with the most awards are the ones that invest the most in their people. This is important for the successful delivery of a likeable offering that will engage the consumer and satisfy his/her needs.

Kefallonitis (2015) identified problem areas that may influence an airline's profile. These areas may be associated with language barriers, message delivery methods and cultural sensitivities. Such challenges cause passenger confusion due to the complexity of the different communication channels and media used to get the message across. Gregorie, Salle, & Tripp (2015) argued that online venues provide the foreground for customers' complaints to take place.

Travel industry communications are no longer serving the practical purpose of simply informing passengers. Engaging the connected passenger in an emotional and experiential way is equally important through the use of brand characteristics

(Aziz, Kefallonitis, & Friedman, 2014). Social media has extended the virtual presence of travel-service providers not only through websites but also through a number of online platforms and applications (Yang, 2014). Social media presence is seen as an extension of a company's virtual self and accounts for corporate image and reputation (Dijkmans et al., 2015; Sodeman & Gibson, 2015). The connected traveller shows preference to travel brands that are more realistic and meet their immediate needs (Hoffman, Novak, & Li, 2015).

Facebook, Twitter and a numerous of mobile device applications have transformed how airlines, hotels and so on engage and interact with their audience. Yet, these new avenues of communication present their own challenges (Figure 1). The airline offering is often understated, commoditized or does not meet travelers' needs. Some media platforms used to promote airlines do not highlight differential advantages but advertise a generic overview of the airline product. The above tactics make passengers think that airlines do not pay attention to their needs and seem disinterested.

Nowadays travel service providers have little or no control over the ways that passengers express their satisfaction or dissatisfaction (Schweitzer, 2014). The concept of sharing information among connected passengers has a much greater potential (Gal-Tzur et al., 2014; Mutum & Ghazali, 2014).

Customizing the entire experiential process provides an answer to personalized service. Marketing campaigns of travel industry service providers should emphasize the service characteristics that loyal passengers prefer (Akamavi, Mohamed, Pellmann, & Xu, 2015; Curras-Perez & Sanchez-Garcia, 2015). Besides a pleasant travel experience, innovation, and comfort, airlines can

greatly impact passenger satisfaction by introducing unexpected “bonuses” that delight customers (Chow, 2015).

Often little things can have a great impact on passenger experience (Gault, Corsar, Edwards, Nelson, & Cottrill, 2014). As an example, the recognition of passenger’s loyalty by offering an upgraded meal service to someone flying in economy class over a long-haul flight would be memorable. Other examples utilized are: premium quality food and snacks in cooperation with premium local food/drink providers, onboard chefs, complimentary giveaways, and specialty events such as inflight live music performances. Positively surprising a passenger with something unexpected works as a catalyst in making a passenger happy and loyal. Equally important to the above is the positive interaction among consumers. Satisfied travellers will mention positive things about an offering online via the use of social media (Dessart, Veloutsou, & Morgan-Thomas, 2015), besides sharing this with another consumer, friend, colleague. Encouraging and rewarding positive offline/online consumer-to-consumer interactions would help create loyalty (Nadeem, 2015) and would be beneficial for any travel-related service provider (Pranter & Martin, 1991).

In an age when airlines are reducing passenger services, other product and service providers are asked to bridge the gaps. Credit cards offer travel insurance benefits, priority boarding and lounge access that enhance the airline experience. Membership programs offer door-to-door baggage handling. Air travel today is less about formal relationships between passengers and specific airline brands and more about multi-connected relationships.

Other innovative examples of social media applications and tools that excite passengers and make travel brands stand out in competition follow:

- A new trend in social media, encourages the simultaneous use of a number of applications. The social media awards Skifties for travel brands have been initiated where

a multi-platform approach on integrating social media is encouraged. In 2015, Turkish Airlines employed such an approach for its advertising campaign where key influencers on social media that their audience follows contributed to advertise the airline via social media platforms. Another participating travel brand in the social media awards, the “Visit Las Vegas” social media campaign streamlined a variety of applications that included Facebook, Instagram, Pinterest, Twitter and YouTube. The campaign orchestrated and communicated several social-media-only events. The organizers carefully targeted users and encouraged them to use interactive material such as videos, pictures and infographics to further engage others and increase traffic as was the case with Turkish Airlines social media winning advertising campaign.

- A popular social media application in the USA is the United Airlines application. It enables a United Airlines passenger to make or alter a flight reservation, check frequent flyer details and get real-time updates on flights or upcoming travel. It helps the check-in for a flight, check bags and locate airport club locations. In addition it serves as the airline’s onboard entertainment device. Passenger can use the app to stream movies and TV programs directly to their handheld device upon connecting to the aircraft’s wi-fi. Last it helps users get a transfer for their destination airport to their desired location using Uber.
- **Etihad:** The option to self check-in a hold-luggage bag using an airline app (ios/android).
- **Swiss Air Lines:** The option to check your hold baggage at home and print baggage labels using your own printer.
- **EVA Air and Hello Kitty Jets:** Taiwanese hospitality with a Hello Kitty® twist. One of the most powerful co-branding concepts in the airline industry. The way EVA Air

of Taiwan have associated Hello Kitty® brand to the airline, offers the airline an advantageous position. Passengers recognize this unique association and connect the Hello Kitty® brand to EVA Air.

- **Icelandair:** The airline prides itself in creating a distinctive Icelandic flying experience. All aspects of passenger service introduce the passenger to an aspect of Icelandic culture, life and traditions. The highlight of their experience is the cabin mood lighting that resembles the northern lights. A campaign that encourages Icelandair passenger to stop in Iceland for a brief period of time went viral on social media as #mystopover

Overall, there are a number of challenges regarding the use of social media in the travel industry:

Challenges:

1. The increasing number of social media channels and applications.
2. Privacy and security concerns regarding user profiles.
3. Staying up-to-date with changing norms and educating users and audiences who follow and engage with social media platforms.

FUTURE RESEARCH DIRECTIONS

Travel brands that hold accumulated equity, built through high advertising expenditures are more likely to be perceived by consumers of superior quality (Aaker, 1996; Guihong & Yu, 2014; Hwang & Hyun, 2014), and therefore satisfy the consumer, in this case the connected-passenger (Esu & Anyadighibe, 2014). Travellers use brand names and product attributes as a source of information about product performance (Hutchinson

and Alba, 1991; Kucukusta, Heung, & Hui, 2014). Communicating these attributes through the use of connected communities has the potential of greater online exposure and word-of-mouth.

This becomes of significant importance if we consider the drop in popularity of TripAdvisor website upon the announcement of teaming up with Priceline (Lorenzetti, 2015). This shows the value that user-generated websites have over corporate-generated information. The power and value of user-generated travel websites need to be explored further.

Travel-related brands and their offerings are less about names and identities and more about people. This is achieved with a view to consumer needs and wants and adjustment to core values, offering abilities and future plans of the company. After all, consumers prefer brands that are realistic (Johnson, 2002). In addition, the environment in which interactions between travel-related providers and connected-passengers need to be such that will generate exciting and therefore satisfaction (Zhu & Chen, 2015). The link between realistic travel brands and the level of satisfaction of the connected passenger needs to be examined.

The connected online communities have the potential of meeting some of the policies and needs of the transportation (Gal-Tzur et al., 2014) and tourism industries, with regards to engaging the customer and offering up-to-date solutions or answers (Misopoulos, Mitic, Kapoulas, & Karapiperis, 2014). There is some evidence on the role of social-media and the connected communities regarding the impact on strategic planning of travel-related companies but this needs to be researched further (Venkataraman & Das, 2014).

Kim & Law (2015) call for research on the role of smartphones in travel and tourism. Smartphones can be further used by firms and tourists to communicate and share information since they have not been used to the degree that they could be employed.

CONCLUSION

The chapter illustrated that connected passengers search for travel-related information and in doing so develop a sense of belonging in social-media networking websites reinforcing the need for dialogue between airline companies and passengers. There are opportunities for the connected passenger in the travel industry available via the user-generated content and the freedom that the passenger has to create material in the online communities and platforms as has been discussed.

Travel industry brands should go beyond the purpose of reflecting a certain ideology and advantages. Travel companies' purposes are to connect to passengers by demonstrating that they are close to them and create emotional ease and comfort. The values of quality and service are expected to be present and taken for granted. Service excellence is not an element of added value any longer. Travel firms create and support the creation of an emotional world around their brand by creating and projecting lifestyles. This lifestyle is a story that customers can associate with, react to or even something they can object to.

KEY TERMS AND DEFINITIONS

Connected Passenger: A passenger who uses Internet-based technology to acquire travel-related information directly through the service provider (airline, hotel) or indirectly through online-communities (Twitter, Facebook).

Multi-Platform Social Media Advertising Campaign: Simultaneous integration of internet-based innovative communication tools that bring users together and advertise companies' communication messages.

Online Communities: Online groups of connected individuals of similar interests, ideas, beliefs and habits.

Travel Industry: This is the industry that is responsible for the transportation of people and goods from one location to another. Travel may be defined as domestic or international and vary in duration. It can also be distinguished as business, recreational, or religious. Travel providers may include airlines, rail and coach operators among others.

Evaluative Dimensions of Urban Tourism in Capital Cities by First-Time Visitors

Annamaria Silvana de Rosa

Sapienza University of Rome, Italy

Laura Dryjanska

Sapienza University of Rome, Italy

Elena Bocci

Sapienza University of Rome, Italy

INTRODUCTION

Information science and technology have a tremendous impact concerning a place, given the fact that online resources, such as websites, portals and engine searches shape the potential and future visitors' expectations. Numerous factors converge when it comes to evaluating such a complex scenario, yet most often tourists are asked to rate their experience on a scale or a series of scales. Although such data appears as fairly easy to gather and analyze, it does not reflect various dimensions of the encounter with the city, including aspects mediated by technology. In order to provide a deeper, social psychological view of the evaluative dimensions of urban tourism, the theory of social representations (Moscovici, 2000) offers a sound epistemological foundation. It has a long tradition, after its birth more than a half a century ago (Moscovici, 1961), of focusing on how people perceive places and cities in particular (Milgram, 1984). However, the theoretical construct of social representation in tourism from a geographic perspective (considering geo-cultural differences between urban locations) has not yet been fully developed, in spite of the fact that various scholars have been applying it to guide empirical research (D'Hauteserre, 2010; Monterrubio & Androtis, 2014). For example: de Rosa and colleagues for decades have worked on social representations of European capital cities and place-identity

among first-visitors from different nationalities (de Rosa, 1995, 1997, 2013; de Rosa, Bocci, & Dryjanska, in press; de Rosa, Bocci & Picone, 2013; de Rosa, & D'Ambrosio, 2011). Moscardo (2011) has concentrated on social representations of tourism planning; Lai and colleagues have applied the construct of social representations of services in context of a national park (Lai, Hsu, & Nepal, 2013), while Dickinson and Dickinson (2006) considered the social representations of transport in tourism.

The strength of the theory of social representations applied to urban tourism lies in its interdisciplinary approach that bridges sociology and psychology, based on the premise that social reality is being continuously constructed (Wagner, 1996). Technology has certainly transformed urban tourism, not only concerning online sources of information, but also when it comes to using smartphones for photographs and video-conversations that add a new dimension to interpersonal virtual communication about the city. In such a dynamic scenario, social representations undergo transformations and as a consequence their evaluative components change.

The online tourism domain integrates a number of theoretical perspectives, including: the *industry perspective*; (2) the *symbolic representation perspective*; (3) the *travel behavior perspective*; and, (4) the *travel information search perspective* (Xiang et al., 2008). Their research demonstrated

that the representations change through technological interfaces, i.e., a search engine, reflecting the idiosyncratic nature of destinations and travelers' heterogeneous information needs when considering IT applied to urban tourism (Xiang, & Gretzel, 2010).

The aim of this chapter is to provide such a multi-dimensional outlook on the evaluation, including not only the internet and the collection of data electronically, etc., but especially the impact of the interactive sources as social media, rooted in the dialogical epistemology that permeates the theory of social representations (Markova, 2000). In particular, whether reality confirms the expectations of tourists concerning a place influences the outcome of this process. In order to explore concrete examples, this chapter concentrates on how tourists evaluate historic capital cities of London, Madrid and Warsaw, emphasizing the difference between initial technologically-mediated virtual expectations and actual first-hand experiences. As demonstrated by Tussyadiah and Fesenmaier (2009, p.37): modern technology, such as videos shared on YouTube.com (and potentially other such sites) can be regarded as a means of "transportation" to destinations, and "facilitating the sharing of such experiences through videos can be viewed as a process of opening or providing access to (realistic and imaginative) tourist experiences".

BACKGROUND

Social representations have been described by the founder of the theory, Serge Moscovici, as "system(s) of values, ideas and practices" (1973, p. xiii). A group of renowned scholars in the field has proposed the following definition to further clarify the term: a social representation is the ensemble of thoughts and feelings being expressed in verbal and overt behavior of actors which constitutes an object for a social group (Wagner, Duveen, Farr, Jovchelovitch, Lorenzi-Cioldi, Marková, & Rose, 1999).

A wide range of research tools, from structured to open has been implemented in this research in order to examine the interactions between expected results and methods, taking into account diverse constructs, such as place-identity, time, space and place-memory.

Methodology

Research Participants

The data has been collected in 2011-2013 in three capital cities: London, Madrid and Warsaw from the total of 420 participants from seven different EU and extra-EU countries (France, Germany, Italy, Poland, Spain, United Kingdom and United States). Each respondent, contacted using the snowball sampling technique, was visiting the city for the first time. On a voluntary basis, the participants filled out *questionnaires in their native language*, starting from *socio-demographic information*, reason of residence in their current location and the additional reasons for visiting the city apart tourism (study, work, etc.). It is important to notice that even the first-visitors, who had additional reasons other than tourism, actually spent their time dedicated to sightseeing and other typical tourist activities, in line with the contemporary trend that urban tourism is often interwoven with other activities, such as business meetings, conferences or studies. Concerning gender, two thirds of participants are women in case of each city. According to age, the research participants have been categorized in three groups: less than 26 y.o.; 26-40 y.o.; 41- 60 y.o. The average age was 27 for London, 26 for Madrid and 34 for Warsaw.

Multi-Method Research Tools

In line with the *modeling approach*, different tools are applied to detect the social representations and their evaluative components within the multi-method questionnaire - created according

to the goals of the investigation and validated in the first wave research on Rome (de Rosa, 1995, 1997, 2013b).

In this chapter, we refer to a selection of results first based on the tools relevant for the *informative and evaluative components of social representations* are considered. On the one hand, the Likert scales from 1 to 10 have been applied to assess the ‘*self-rated importance of sources of information about the city*’, differentiating between school/university, novels and poetry, movies, songs, Internet, newspapers and magazines, tourist guidebooks, documentaries and interpersonal communication, and specifying the details. In particular, modern information science makes it possible to consult multiple types of sources through technology available on smartphones, tablets and computers. On the other hand, comparing ‘*lists of adjectives that describe the city*’ makes it possible to obtain additional evaluative dimension of social representations.

Then, we discuss the results of the “*associative network*”, a graphic-projective technique developed by de Rosa (2002) to specifically study the structure, contents and polarity of the semantic field of specific social representations. It includes as stimulus word the “*city target of the tourist destination*” with no limit in the number of associations evoked at the imagined level and with the ramification between words and connections between trees of words in the semantic space. ‘*Associative networks*’ include the stimulus words ‘London’, ‘Madrid’ or ‘Warsaw’ (corresponding to the respective capital city destination of the groups of the first-time visitors interviewed). The value of such open technique is that it allows for the visitors to include their impressions directly related to information science and technology, including images from sources such as social media, the internet and the collection of data electronically, etc.

The data analysis using descriptive statistics and multivariate techniques, in particular lexical correspondences analysis with the software package SPAD-T allows relating the different

participants’ groups identified on the basis of the *illustrative variables* with the semantic space, positioning them on the representation field determined by the *active variables* of the evoked words through the associative networks.

UNDERPINNING EVALUATION THROUGH SOCIAL REPRESENTATIONS

Knowledge about European capitals forms a part of cultural baggage in many parts of the world thanks to education, mass media and other forms of communication, mediated through modern technology. Paired with natural activities of gathering additional information prior to the trip, especially concerning practical details, social representations of these specific destinations appear as complex and multi-faced. For instance, a movie may provide positive impression of the city and actually induce tourism (Beeton, 2005) or, on the contrary, it may portray a place as grim and dangerous. Evaluation is influenced by such indirect perception, whether or not direct experience confirms it. In this case, Figure 1 demonstrates that on average the participants declared the highest level of knowledge about London, followed by Madrid and Warsaw.

In fact, how people perceive a place depends on their characteristics, as well as the level of information from different sources. For London and Madrid the highest importance was assigned to interpersonal communication, while for Warsaw – to Internet. The increasing relevance of electronic texts and images of tourist destinations easily found on the Internet may be treated both as a source of information for the researchers (Brunet, Bauer, De Lacy & Tshering, 2004) and as a target to be shaped in order to promote urban tourism.

The *associative networks* (de Rosa, 2002) offer insight to different attitudinal dimensions of the social representations including assessment, which is detected by the assignment of a positive, negative or neutral value to every elicited word. In this way, the evaluation of the word does not depend

Figure 1.

on the researcher but on participants themselves, who place a plus, minus or zero next each word. Based on averages, polarity index can be calculated per each associative network or for the city as a whole; in any case its value ranges from -1 to +1. Here the polarity index is applied in two ways: first the average values are considered for each city in order to get a general idea, and then - the polarity index embedded in the most significant factors for each city.

The average polarity indexes are: 0.502 for London, 0.599 for Madrid and 0.416 for Warsaw. The above figures do not represent a direct evaluation of the cities on a classic Likert attitudinal scale, but stem from the projective nature of associative networks detecting freely words evoked. Therefore, first-time visitors to all of the capitals predominantly elicit terms that they rate as positive with each one of the cities; while for Madrid the proportion of this positive rating is the highest, London comes on the second place and Warsaw – third. These results are due to the basic characteristics of each city that are

not subject to change, for example in realms of climate and history, as well as other factors that can be influenced in order to promote sustainable tourism. Weather conditions clearly favor Madrid, since participants rate as positive such words as ‘sun’ and ‘warm’, while they lower the polarity index of London (negative value of the word ‘rain’) and Warsaw (negative value of the word ‘cold’ and ‘freezing’). History has a strong influence on social representations of Warsaw that consist of phenomena related to World War II, destruction, tragic history of the Jews and communism, rated as negative. However, functional aspects that relate to sustainable tourism are quite frequently mentioned and, as opposed to the weather and history, may be further promoted (if positive) or changed (if negative).

Based on the associative networks, not only polarity indexes are helpful to understand how first-time visitors evaluate the city, but also the main factors offer some insight into indirect assessment, with the advantage of having the positive, negative or neutral significance assigned to each

Figure 2.

term by the participants themselves. Figures 2-4 represent the structural organization of the semantic field evoked by free associations. The factors were extracted by multi-dimensional analysis of the lexical correspondences of words evoked by the participants in the associative networks. The scale of the axis varies from 0 to 2 demonstrating different profiles of replies; Chi-square distances between profiles can be observed in ordinary physical (or Euclidean) space, by transforming the profiles before plotting, or by stretching the plotting axes by different amounts, so that a unit on each axis has a physical length inversely proportional to the square root of the corresponding element of the average profile (Greenacre, 1993).

Figures 2-4 are the graphic representations of the first most important factor and the major elements of the second one, which organize the

representational field detected via *associative network*.

The first factor is located exclusively on the positive horizontal semi-axis and consists of words 'nightlife', 'pollution', 'fun' and 'expensive'. The second factor contains numerous words on both semi-axes, to the point that makes a legible graphic representation of all of them impossible. For this reason only the four most significant words are displayed: 'efficient' and 'amazing' on positive vertical semi-axis and 'multicultural' and 'music' on negative vertical semi-axis. In social representations of London, evaluation focused on these elements plays an important role. The participants give high importance to 'pollution' in London, marking it as negative, yet typical for the city. Another outstanding characteristic of London is its economic perception as 'expensive',

Figure 3.

seen as negative. Probably equitable access to the city seen as a common resource is made much more difficult when prices are high. On the other hand, the rest of main associations with London is rated as positive, especially in relation to two main areas, concerning respectively socio-recreational and functional dimensions: 'nightlife' and 'efficiency'. Clearly, while from the point of efficiency visitors and residents may have similar positive expectations as users of public transportation and infrastructure, nightlife too assumes a positive connotation, when occurring together with 'music' and 'fun'. Indeed it plays a significant role in case of urban tourism, as we may also observe in Figure 3 that graphically displays the first three words of each dimension of the first two most significant factors for Madrid.

The first three words of the positive semi-axis of the first factor overlap with those of the negative semi-axis of the second factor: 'Franco', 'Atocha' and 'movida'. It is interesting how each one of them actually forms a part of different aspects of reality, rated from negative through neutral to positive. Thus, evoking the social memory of dictatorship, participants assign to 'Franco' negative connotations, which is also true in case of 'strikes', considered as an efficiency problem that renders the city less visitor-friendly. Other aspects that also affect functionality, such as the main metro station 'Atocha' or Madrid's collocation in a hot climate tend to be evaluated in positive terms. Elements related to history, 'monuments' and 'discovery' receive positive assessment, appreciated by tourists. As for London with nightlife, in

Figure 4.

case of Madrid the research participants opt for ‘movida’ and ‘Erasmus’ (in line with their young age and the most common target destination for international student’s mobility). In general, both factors for Madrid appear as articulate and diverse, pointing to multiple aspects of the city’s life and history. In geographical terms, the first-visitors interviewed seem to appreciate the hot climate and collocation in Southern Europe. While visitors do not mention elements related to ecology of the city, they demonstrate knowledge of local customs and language by referring to certain phenomena directly in Spanish, which may evidence respect and friendly approach to residents.

The history of the city plays an important role also in case of Warsaw and seems familiar to the visitors, as graphically displayed in Figure 4, that shows the most significant words (‘Uprising’,

‘Kaczynski’ and ‘Palace of Culture’ – negative semi-axis; ‘safe’, ‘clean’ and ‘tidy’ – positive semi-axis) (that constitute the first factor, as well as all six words (‘dangerous’, ‘interesting’, ‘Golden Terraces’, ‘colorful’, ‘nature’ and ‘beautiful’) that constitute the entire second factor concentrated in the positive vertical semi-axis.

In fact, ‘Uprising’, ‘Kaczynski’ and ‘Palace of Culture’ all point to three different periods of history of Poland: World War II rated as negative, recent history as a democracy under President Kaczynski himself rated as positive although dead in controversially represented circumstances in Smolensk (Dryjanska, 2011) and communism rated as negative. On the other hand, the first three words in the positive semi-axis of the first factor, ‘safe’, ‘clean’ and ‘tidy’ clearly indicate functional aspects of life in the city evaluated in

positive terms. However, very high relevance of the negatively rated word 'dangerous' in the second factor demonstrates that the functionality of the city is not only seen in positive terms. 'Golden Terraces', a place with a highly functional character as a modern shopping center located at the central train station in Warsaw, tends to receive positive evaluations from first-visitors. The third major dimension identified relates more closely to environment perceived as positive, as evidenced by the presence of words 'nature', 'interesting', 'colorful' and 'beautiful'. Tourists seem to appreciate these aspects of the city, and it would be interesting to extend our study to know if these evaluations are in line with fast developing information technology and web-based preferences.

All the three graphs above presented show not only the contents and structure that organize the social representations of the three target cities, but also the different positioning of the "illustrative variables" in the representational field, that clearly shows the meaningful role played by the socio-demographic variables selected, including gender, age, nationalities and reason for the visit experience. An analytical reading of these results would allow more detailed interpretation of the anchoring of social representations into specific social groups. Here we limit to underline very briefly that males elicit more often socio-recreational places, like 'nightlife' in London and 'movida' in Madrid, while females emphasize functional characteristics of the city (for example Warsaw as 'tidy', 'clean' and 'safe'); domestic first-visitors (Yang & Wall, 2009) mention more precisely buildings significant for the history of their own country (for example the Polish visitors in Warsaw), while first-visitors from other countries are more attracted by functional dimensions and natural environment (for example British mention 'nature' in Warsaw, while Italian and German focus on the city's evaluation as 'tidy', 'clean' and 'safe').

In spite of the similarity, a change occurs in representations after the visit. The major change

that occurred in the social representation of Warsaw is interesting since in case of this city modern information and technology channels, such as Internet, has come to play the most important role. For example, among modern sources of information, travel blogs (Schmallegger, & Carson, 2008) virtual communities, wikis, social networks, collaborative tagging, and media files shared on sites like YouTube and Flickr (Gretzel, 2006) have started to change approached to information exchange about tourist destinations.

The top frequent adjectives used to evaluate the three different European cities and their historic centers tend to be quite similar. It is also interesting that especially for London and Madrid the visitors use adjectives that could apply to virtually any European capital, which enables us to easily compare them. The adjective with a clear positive evaluative component is 'beautiful', and in case of Madrid it has the highest frequency, especially after the visit. The data demonstrates that the experience of visiting the city tends to enrich social representations by adding to their complexity and in general has a positive influence on evaluation. Warsaw tends to be perceived in the most negative way, as demonstrated by the presence of such adjectives as 'sad' and 'dirty', although in some cases in contrast with opposite evaluations, like 'lively' and 'clean'.

DISCUSSION

Overall, the evaluation of the same city by the same person sometimes gives different results depending on the method and its structured versus projective nature. Whether a person is asked to use a scale, an adjective or a word to which he or she assigns a positive, neutral or negative value does matter, as evidenced by the 'modeling approach' to the study of social representations, which integrates different methods and techniques coherently with the articulation of different theoretical constructs (like in this study place-identity, attitudes, prior

knowledge and channels of information, etc.) and dimensions (informational, evaluative, emotional, imaginal/experiential, etc.).

Different dimensions of evaluation of the capital cities under scrutiny are taken into account by asking the first-visitors to evoke adjectives and by calculating polarity indexes of the semantic space projected in *associative networks* (de Rosa, 2002, 2003, 2005).

The evaluation of a city by first-time visitors is based on the interplay of expectations (the social representations of the city before the visit) and actual experience. Thus, the “city’s evaluation” after the visit already encompasses “prior knowledge”, rated on Likert scales from 1 to 10, for each source of information: school/university, novels and poetry, movies, songs, Internet, newspapers and magazines, tourist guidebooks, documentaries and interpersonal communication. It may also be expressed in a different way by freely using adjectives to describe and represent the city. Following the direct experience, associative networks envision social representations of the city, also providing information about its polarity index (to which degree it is seen in a positive, neutral or negative way) and the main factors that reveal the organization of its semantic space. Such integrative framework may be applied to analyze the evaluative aspects of urban tourism in a more profound, structured way, taking into account different aspects. It also allows the researchers to compare how first-time visitors assess different cities or how the evaluation of a given city changes over time.

To sum up, different preferences for top places in London, Madrid and Warsaw may be observed demonstrated by first-visitors from seven distinct nationalities, outlined in the Figure 5, in line with the cultural differences and styles of relation between tourists and their preferred places already detected in the first-wave research on Rome (de Rosa, 1997, 2013b).

Certain elements of the proposed integrative framework are already well known and applied in research on urban tourism, as for example the

Figure 5.

differentiation between pre- and post-visit images of the city (Ben-Dalia, Collins-Kreiner & Churchman, 2013). However, the strength of the modeling approach lies in its capacity to integrate in an organized rationalized and justified way various methods coherently with the multiple theoretical constructs that social representation pretends to articulate (compared to the fragmentation of the micro-paradigms in the mainstream social psychology tradition: Moscovici, 2000). A deep understanding of how visitors evaluate a city can be helpful when trying to form new models or attempting to predict future patterns, based on socially constructed understandings of risk and adventure in the context of urban tourism (Beedle, 2005).

CONCLUSION

The theory of social representations offers a holistic view of socially constructed reality, acknowledging that the perception of a destination is dynamic. Therefore, periodic monitoring and adjustment of decisions appear necessary, also in order to be aware of new niche markets, for example based on performing arts (Lim & Bendle, 2012) or interest in communist past of

a city. Eventual evaluation is a two-way street, based on expectations and previous knowledge, as well as the actual experience. Therefore, there is a clear need to intervene both during city-branding, when shaping the image of a city for example through its website or other available materials, and by investing in the infrastructure, services and preparation of local population. One has to be careful not to limit the decisions to the supply side of urban tourism that takes visitors for granted and tries to modify their behavior once at the destinations (Dolnicar, 2006). Exploring the evaluative dimension of social representations of cities helps to gain insight into visitors' expectations and preconceived ideas in the light of fast developing information technology.

Overall, the theory of social representations has much to offer in order to enrich the underlying socio-psychological perspective of research on urban tourism in a new light of technology.

FUTURE RESEARCH DIRECTIONS

Future research directions shall emphasize even more technology and new media as vital for urban tourism (see the additional readings below cited), integrating and comparing several interrelated research lines, as we have tried to develop combining the field study and the new media studies on *Place @-branding and European Capitals*, including analysis of 'city visiting cards' via municipal websites, comparison of preferred itineraries of past visitors with virtual tours by potential first-visitors flying with Google Earth, analysis of conversational exchanges about city-places experienced/imagined via social networks, institutional stems and online commercial logos of the cities (de Rosa, 2013b; de Rosa, Bocci & Picone, 2013; de Rosa & Bocci, 2014). Other possibilities that we are currently developing look at the urban destinations' evaluations via YouTube and travel forums such as Trip Advisor or looking at augmented reality tourist experiences.

These kind of the studies, theoretically-driven by the *modeling approach* to Social Representations, also taking into account the whole phases of the tourist life-cycle (pre-trip, on-site and after-trip-phase), may be in future research directions integrated with the new trend of data-driven studies, based on *big-data business intelligence* and *knowledge management* in the society of algorithms and machine-generated data also including the related critical questions (boyd & Crawford, 2012; Parks, 2014) and those on the impact of mobile *augmented reality* interfaces and user-centered designs on decision-making based on fast retrieval of information by tourists exposed to unfamiliar environments (Tussyadiah & Zach, 2012).

KEY TERMS AND DEFINITIONS

European Capitals: Capital cities in Europe, containing an area that can be identified as a historic center (sometimes called “Old Town”, like in the case of Warsaw).

First-Time Visitors: People who visit a given place (for example a city) for the first time in their lives (sometimes also called first-time visitors).

Geo-Cultural Context: Specific geographic location that takes into account the cultural characteristics of inhabitants, such as common language, history, customs or art; for example, insular, Mediterranean or North-European geo-cultural contexts.

Modeling Approach: A paradigmatic approach to social representations developed by A.S. de Rosa (2013a, 2014) that integrates different methods and techniques coherently with the articulation of different theoretical constructs and dimensions.

Place-Identity: A construct created by H.M. Proshansky (1978) that links both spatial and temporal dimensions of identity, reflecting social aspects of built and natural environment.

Social Representations: A complex construct created by Serge Moscovici (1961), which – according to de Rosa (1994) can be operationalized on three different levels: a) social representations as *phenomenon*; b) *theory* of social representations; c) *meta-theory* of social representations.

Urban Tourism: A form of tourism aimed at visiting a city while traveling for recreational purposes.

Fifty Shades of Dark Stories

H**Lea Kuznik***University of Maribor, Slovenia*

INTRODUCTION

Dark tourism is a special type of tourism, which involves visits to tourist attractions and destinations that are associated with death, suffering, disasters and tragedies venues.

Visiting dark tourist destinations in the world is the phenomenon of the twenty-first century, but also has a very long heritage. Number of visitors of war areas, scenes of accidents, tragedies, disasters, places connected with ghosts, paranormal activities, witches and witchhunt trials, cursed places, is rising steeply. Reasons and motives for the visit are varied. Dark tourism has been recognised as a distinctive tourism phenomenon of the twenty-first century, with increasingly significant numbers of visitors and tourists going to dark tourism attractions and sites, new dark tourism products and attractions emerging, and modern global communication media generating interest in dark tourism attractions, while at the same time affecting the image of destinations. The phenomenon of dark tourism has been examined in academia from the mid-1990s. Since then, study of this phenomenon has increased, and the scales of relevant studies have been enlarged.

Dark tourism in Slovenia is very poorly developed comparing to the world and it is mostly limited only on tourist sites connected with both wars. Therefore the theme is a novelty in Slovenia, as well as in Slovenian professional and scientific literature where is almost unknown.

The main purpose of this article is to explore the current situation of dark tourism and propose a typology of dark tourism in the world and in Slovenia, which should serve as a basis for further efforts in the design of a new dark tourism products based on the dark heritage in Slovenia

and other countries, as shown below in the case of witchcraft.

The research is based on in-depth analysis of literature and fieldwork in Slovenia which contains the method of unstructured interviews with curators in Slovene Ethnographic Museum, Museum of Ribnica and Celje Regional Museum as well as the method of observation with participation in a guided tour through the exhibition at Ljubljana Castle: The Barbarism of Torture.

BACKGROUND

The term dark tourism was coined by Foley and Lennon (1996: 198) to describe the attraction of visitors to tourism sites associated with death, disaster, and depravity. Other notable definitions of dark tourism include the act of travel to sites associated with death, suffering and the seemingly macabre (Stone, 2006: 146), and as visitations to places where tragedies or historically noteworthy death has occurred and that continue to impact our lives (Tarlow, 2005: 48). Scholars have further developed and applied alternative terminology in dealing with such travel and visitation, including thanatourism (Seaton, 1996), black spot tourism (Rojek, 1993), atrocity heritage tourism (Tunbridge & Ashworth, 1996), and morbid tourism (Blom, 2000). In a context similar to »dark tourism«, terms like »macabre tourism«, »tourism of mourning« and »dark heritage tourism« are also in use. Among these terms, dark tourism remains the most widely applied in academic research (Sharpley, 2009).

The concept of dark tourism is in contrast to marketing slogans that prefer the broader promotional aspect and call this type of tourism »historic

DOI: 10.4018/978-1-5225-2255-3.ch353

tourism«. Major encyclopedias of tourism identify »dark tourism« also as »thanatourism«, in which the core meaning of the term relates mostly to visits to the tombs, cemeteries and memorials of prominent people (Gosar, 2015a).

Although this is a newer type of specialized tourism, researchers can speak as one of the oldest types of tourism, because death is historically always attracted human inquisitiveness. Some kind of organized »thanato tourism« were already gladiator games in the Coliseum of ancient Rome (Gosar, 2015b). Popular festivals in the past have been a public hanging, beheading and burning of witches. Walking and paid visits to the battlefield at Waterloo in Belgium, the place of Napoleon's last battle between the English nobility had been ongoing since the time of the battle in 1815. Therefore the kind of dark tourism has a very long heritage.

Dark tourism relates to tourist travel, which interprets the heritage through tragedies and conflicts and is raising awareness of dark historical realities, or the heritage of it (Stone, 2013). The central research centre for dark tourism is located at the University of Central Lancashire, in England. The Institute for Dark Tourism Research (iDTR) is led by Dr. Philip Stone. According to iDTR, the main contours of dark tourism destinations are to be found in three groups of geographically expressed areas: destination of the death, burial, and/or the tragedies of celebrities, destinations of great battles and falling soldiers, destinations of collective suffering and death.

Visiting such sites can play a significant part in a tourist's experiences, and in turn, that there will most probably be anxiety about the development of these sites as tourist attractions (Ashworth & Hartmann, 2005; Ryan, 2007; Sharpley & Stone, 2009; Wilson, 2008). These concomitant aspects of dark tourism have indeed lead to concerns about the morality of commodifying death, disaster, and atrocity (Lennon & Foley, 2000; Seaton, 2009).

All the actions associated with the tourism trips that expose/define the places associated

with death, suffering and/or everything that is reminiscent of the grim period of mankind is to be related dark tourism (Stone, 2006). According to researchers of iDTR, dark tourism is a subcategory of the historic tourism, which includes the content of the material and intangible heritage, as both strengthen our historical memory.

Different Shades of Dark

Dark tourism has been also called place-specific tourism (Ashworth & Hartmann, 2005: 4). As such, several researchers have classified dark tourism sites according to their defining characteristics.

Miles (2002) proposed a darker-lighter tourism paradigm in which there remains a distinction between dark and darker tourism according to the greater or lesser extent of the macabre and the morose. In this way, the sites of the holocaust, for example, can be divided into dark and darker tourism when it comes to their authenticity and scope of interpretation. The United States Holocaust Memorial Museum in Washington D.C. is associated with death, and thus categorised a dark tourism site only, whereas the site of Auschwitz - Birkenau in Poland possesses a unique location authenticity as a former concentration and extermination camp, and thus site of darker tourism.

On the basis of the dark tourism paradigm of Miles (2002), Stone (2006) proposed a spectrum of dark tourism supply which classifies sites according to their perceived features, and from these, the degree or shade of darkness (darkest to lightest) with which they can be characterised. This spectrum has seven types of dark tourism suppliers, ranging from Dark Fun Factories as the lightest, to Dark Camps of Genocide as the darkest. A specific example of the lightest suppliers would be dungeon attractions, such as London Dungeon, or planned ventures such as Dracula Park in Romania. In contrast, examples of the darkest sites include genocide sites in Rwanda, Cambodia, or Kosovo, as well as holocaust sites such as Auschwitz - Birkenau.

REASONS FOR VISITING DARK TOURISM SITES

There are a number of reasons for travelling to dark tourism sites, which most simply can include curiosity, education, survivor guilt, remembrance, nostalgia, empathy, and horror (Ashworth & Hartmann, 2005; Baldwin & Sharpley, 2009; Garwood, 1996; Lennon & Foley, 2000; Miles, 2002; Smith, 1996). Each of these can be discussed separately as follows:

1. Curiosity

Many tourists are interested in the unusual and the unique, whether this be a natural phenomenon (e.g. Niagara Falls), an artistic or historical structure (e.g. the pyramids in Egypt), or spectacular events (e.g. a royal wedding). Importantly, the reasons why tourists are attracted to dark tourism sites derive, at least in part, from the same curiosity which motivates a visit to Niagara Falls. Visiting dark tourism sites is an out of the ordinary experience, and thus attractive for its uniqueness and as a means of satisfying human curiosity. So the main reason is the experience of the unusual.

2. Empathy

One of the reasons for visiting dark tourism sites may be empathy, which is an acceptable way of expressing a fascination with horror. Ashworth and Hartmann (2005) note that empathy relies upon the capacity of heritage consumers to identify with individual victims of the atrocity. While this identification is assumed to be more with the victims in question, it could equally conceivably be with perpetrators also. In many respects, the interpretation of dark tourism sites can be difficult and sensitive, given the message of the site as forwarded by exhibition curators can at times conflict with the understandings of visitors.

3. Horror

Horror is regarded as one of the key reasons for visiting dark tourism sites, and in particular, sites of atrocity. Ashworth and Hartmann (2005) note that there is a considerable amount of literature, folk stories, and more recently internet, film and television portrayals of scenes of horror which evoke emotions of fear and fascination in consumers. Relating atrocity as heritage at a site is thus as entertaining as any media depiction of a story, and for precisely the same reasons and with the same moral overtones. Such tourism products or examples are: Ghost Walks around sites of execution or murder (Ghost Tour of Prague), Murder Trails found in many cities like Jack the Ripper in London.

4. Education

In much tourism literature it has been claimed that one of the main motivations for travel is the gaining of knowledge, and the quest for authentic experiences. One of the core missions of cultural and heritage tourism in particular is to provide educational opportunities to visitors through guided tours and interpretation. Similarly, individual visits to dark tourism sites to gain knowledge, understanding, and educational opportunities, continue to have intrinsic educational value (Ashworth & Hartmann, 2005). Moreover, a number of sites emphasise the visitors educational expectations in terms of their capacity to learn from past mistakes, for example, the United States Holocaust Memorial Museum in Washington DC. In turn, many dark tourism attractions or sites are considered important destinations for school educational field trips, achieving education through experiential learning (Marcuse, 2005).

5. Nostalgia

Nostalgia can be broadly described as yearning for the past (Dann & Potter, 2001; Smith, 1996), or

as a wistful mood that an object, a scene, a smell or a strain of music evokes (Belk, 1990: 670). In addition however, it has also been recognised as a reason for travelling to dark tourism sites, although not perhaps a key or central motivation. In this respect Smith (1996) examined war tourism sites and concluded that old soldiers do go back to the battlefields, to revisit and remember the days of their youth.

6. Remembrance

Remembrance is a vital human activity connecting us to our past (Young, 1993). Remembrance helps people formulate an identity, allowing them to learn from past mistakes, and to go forward with a clear vision of the future. In the context of dark tourism, remembrance and memory are considered key elements in the importance of sites (Lennon & Foley, 2000; Walter, 2009; Young, 1993). For several sites associated with the holocaust and the Second World War in European cities, commemoration and remembrance are key reasons for their existence.

7. Survivor's guilt

One of the distinctive characteristics of dark tourism is the type of visitors such sites attract, which include survivors and victim's families returning to the scene of death or disaster. These types of visitors are particularly prevalent at sites associated with Second World War and the holocaust. For many survivors returning to the scene of death and atrocity can achieve a therapeutic effect by resolving grief, and can build understanding of how terrible things came to have happened. This can be very emotional experience (Braithwaite & Lee, 2006).

Such reasons for visiting dark tourism sites or attractions can in turn influence visitors on site experiences.

TYOLOGY OF DARK TOURISM

When analyzing a wide variety of dark tourism in the world, depending on the content researchers can give the following typology of dark tourism which can be divided into two levels:

1. Dark places in nature:
 - a. Disaster area tourism (visiting places of natural disaster after e.g. hurricane Katrina in New Orleans, tsunami in Thailand, earthquake in Nepal, sites of volcanic destruction e.g. Pompeii, Montserrat in the Caribbean...).
2. Dark places in connection with people:
 - a. Grave tourism (visiting famous cemeteries, graves of famous individuals, or grand mausoleums of some real cult personality, e.g. Paris Pere Lachaise Cemetery with Jim Morrison and Edith Piaf graves, Taj Mahal in Agra, Sedlec Ossuary in the Czech Republic, Pierce Brothers Westwood Village Memorial Park in Los Angeles with graves of Marilyn Monroe, Roy Orbison and other Hollywood stars).
 - b. War or battlefield tourism (visiting former war places e.g. Napoleon's battle of Waterloo in Belgium, USS Arizona Memorial in Hawaii, Cu Chi Tunnels in Vietnam, the Bridge over the River Kwai in Thailand...).
 - c. Holocaust tourism (visiting concentration camp, memorial sites, memorial museums, former ghettos and sites where the Nazi perpetrators planned it all e.g. The House of the Wannase Conference and Führerbunker in Berlin, United States Holocaust Museum in Washington D.C., Yad Vashem in Jeruzalem, Auschwitz in Poland...).

- d. Genocide tourism (visiting places of genocide e.g. Rwanda genocide, Toul Sleng Genocide Museum and The Killing Fields in Cambodia, the Srebrenica mass killing in Bosnia and Herzegovina...).
- e. Prison tourism (Alcatraz Island in the San Francisco Bay, Canon City in Colorado, Ottawa Jail Hostel, Devil's Island in French Guiana...).
- f. Communism tourism (visiting North Korea, the big four: Lenin, Mao, Ho Chi Minh and Kim).
- g. Cold war and iron curtain tourism (seeking out traces and remains of the Berlin Wall).
- h. Nuclear tourism (visiting sites of civil nuclear disaster e.g. Chernobyl in Ukraine, Fukushima in Japan, sites of nuclear testing e.g. Semipalatinsk in Kazakhstan and Nevada Test Site in USA, or missile silos e.g. Titan Missile Museum in Arizona, and also two places where atom bombs were actually used for real: Hiroshima and Nagasaki in Japan).
- i. Murderers and murderous places tourism (Jack the Ripper in London, Lee Harvey Oswald in Dallas – Visitors can see the sixth floor of the building from which he fired at US president John F. Kennedy – and the Dakota, apartment building in New York City where John Lennon was shot).
- j. Slum tourism (visiting impoverished areas e.g. slums in India, Brazil, Kenya...).
- k. Terrorist tourism (visiting areas e.g. Ground Zero in New York City, The Boston Marathon, the Bardo Museum in Tunis and tourist resort at Sousse in Tunisia...).
- l. Paranormal tourism (visiting crop circles, UFO sightings, the haunted house in Amityville, paranormal activities in Stanley Hotel in Colorado...).
- m. Witched tourism (visiting the city of Salem in Massachusetts...).
- n. Accident tourism (visiting places e.g. Paris tunnel Pont de l'Alma, where the British Princess Diana and Dodi Fayed died in a car accident).
- o. Icky medical tourism (visiting e.g. Josephinum, medical museum with anatomical wax models in Vienna, the Mütter Museum in Philadelphia, Meguro Parasitological Museum in Tokyo and also all the "Bodies Exhibitions").
- p. Dark amusement tourism (visiting amusement parks e.g. the Dungeons exhibitions in London, Dracula theme park, ghost tours in London, Prague, Chicago...).

H

Typology of Dark Tourism in Slovenia

Dark heritage is also the basis for the development of dark tourism in Slovenia. Military cemeteries and ossuaries, monuments and museums, the theater battles execution and solemn memorial events at the anniversaries are an integral part of the European cultural landscape and society. In Slovenia dark tourism destinations include:

- Cemeteries (Zale Cemetery in Ljubljana, Cemetery Pobrezje in Maribor, Roman Necropolis in Sempeter in Savinja Valley).
- Prisons and penitentiaries (Penitentiary at the Ljubljana Castle, Celica Jail Hostel).
- Museums (The Hospital Franja, Park of Military History in Pivka, Kobarid Museum, Idrija War Museum, War Museum in Logatec).
- Concentration camps (Ljubelj, Mauthausen).
- Memorial sites and monuments (Cerje Monument, Monument for the Battle of Drazgose, Monument to Pohorje Partisan Battalion in Osankarica, Teharje Memorial

- Park, The Memorial Church of the Holy Spirit in Javorca, Russian Chapel at Vrsic)
- Fortification systems (Vallo Alpino, Rupnik`s Line, Fortress Kluze).
 - Guided tours of military facilities (Rupnik`s Line, The Hospital Franja).
 - Remembrance paths – (The Walk of Peace, from Alps to the Adriatic, Circular Path of Military History in municipality of Pivka).
 - Shows (The show about First World War at Fortress Kluze performed by Dreizehn Dreizehn Society – 1313. It is a different way of discovering the everyday life of the soldiers on the Isonzo front. Visitors can see tooth extraction, reading the long-awaited love letter, fear, nursing wounded. Every soldier at the front experienced all that, irrespective of their nationality).
 - Performing battles (Rupnik`s Line battle in municipality of Ziri, »Liberation of Primorska 1945« battle in the Park of Military History in municipality of Pivka, both performed by Triglav Cultural and Historical Society).
 - Hiking along the trails of war memories (Memorial march »Along the Trail of the Cankar Battalion«, Along the Barbwire of the Occupied City in Ljubljana).
 - Post-war killings (Kren Cave mass grave, Kocevski Rog mass grave, The Barbara Pit).

The analysis shows that dark tourism in Slovenia is mainly associated with topics related to the First World War and the Second World War period, comprising conventional museum presentations, visiting places “in situ”, performances and thematic trails in conjunction with the two world wars.

ALONG THE TRAILS OF SLOVENIAN “WITCHES”

Beside heritage of war Slovenia can offer different opportunities for the development of dark tourism

on the basis of dark cultural heritage. One of the topics is witchcraft which has a long heritage in Slovenia and it is not yet included in tourism. Women accused of witchcraft were usually burned at the stake, like in four stories of Slovene “witches” described below. All of them could be effectively incorporated into a comprehensive and innovative tourism product.

1. The tragic love story of Veronika of Desenice and Frederick II., Count of Celje.

The first process under the accusation of witchcraft in Slovenia took place in 1427 in Celje against Veronika of Desenice. She was the second wife of Frederick II., Count of Celje. Little is known of her early life. It is believed the name Deseniska derives from the village of Desinic in Croatia, where Frederick also had extensive estates. Veronika was minor nobility and Frederick’s father Hermann II. greatly opposed to the marriage. The chronicles of the Counts of Celje suggest he had his son arrested and, while holding him prisoner, initiated a trial against Veronika accusing her of witchcraft. She was acquitted by the court, but despite this incarcerated in Ojstrica Castle near Tabor and murdered by being drowned. She was buried in Braslovce and a few years later Frederick arranged for her remains to be reburied at the Carthusian monastery at Jurkloster. Her grave was discovered in 2005.

2. The story of Anica at Ljubljana Castle: The Barbarism of Torture - an exhibition of torture devices from the 16th to the 18th century.

The exhibition offers a more detailed understanding of the course of criminal procedures of the time, from jail and interrogation to the execution of the sentence, with the aid of costumed characters – the Ljubljana executioner Hans and his victim Anica, who has been accused of witchcraft in a story that is based on an actual witchcraft trial that unfolded in Ljubljana at the end of the 17th century.

The exhibition of early modern torture devices, tools and requisites, which were used both to achieve a confession of guilt by means of torture and to administer punishment for minor and serious offences, is intended to shed light on the time of the proliferation of torture practices and cruel punishments, while also serving as a reminder that even today these practices are nowhere near being merely a residue of the distant past. Is today's supposedly civilised society any different at all?

3. The tragic love story of Agatha and Friderich Herberstein, count of Hrastovec Castle.

In the 16th century, a young count from Hrastovec, Friedrich Herberstein, fell in love with beautiful Agatha from the Stralek manor. Friedrich's mother opposed to their marriage, therefore the young couple got secretly married in the chapel of Stipler. So, Friedrich's mother accused Agatha of witchcraft. While Friedrich was at war, his mother tortured Agatha and made her throw a new-born baby into the burning stove. Then, she reported the fact to the judge who condemned Agatha to death. Her step-mother demanded that Agatha be beheaded. When Friedrich returned from the war, he could not find his beloved wife. In his grief, he planted a black cross, a symbol of unhappy love, in the ground where the tragedy happened. Today the black cross can be found in Lormanje in Lenart municipality. The story is described in the book "The Black Cross", by Ozbalt Ilaunig.

4. The last one on the stake: Marina Susarek in Ribnica.

The Process of Ribnica was a typical witch process, with the usual accusations - from flying on the Sabbath and making contract with the Devil, which was eagerly advocated by the judge, to accusations of causing damage by witchcraft, partly reported by the people from the village. It is also characteristic that it was a group process in which the accused were forced to inform against

their colleagues, which resulted in new victims. The process was held for at least two years, from 1700 to 1701, but it might have started earlier. The Process of Ribnica resulted in at least seven victims beside Marina Susarek (Kosir, 2001).

Marina Susarek was forty years old, mother of six children, married to the shoemaker. She was accused of witchcraft and put on the witchcraft chair to confess her guilt. After three hours of torture she admitted to be a witch. She was sentenced to death. They cut off her head with a sword. Her body was thrown on the stake (Kosir, 2001). Records of her trial are kept in the Archive of the Republic of Slovenia.

FUTURE RESEARCH DIRECTIONS

Number of visitors of places of disasters, tragedies and scenes of murder, witchcraft and cursed places is rising sharply. Such places visitors attended previously in history, but this were not called dark tourism.

Irresistibly attractive places of accidents were identified in the tourism industry as a promising market niche. Human inquisitiveness has become a source of income of the organizers of tourist trips, also locals are satisfied who earn some money because of their past disaster.

Dark tourism is in fact often linked to processes of selected memorialization of past violent events, and to a related production of specific geographies of memory. The question is to what extent it is in fact acceptable to market a tragic event, who should deal with destination images created by the media, to what extent tourist and visitor expectations created by the media can in fact be met, and how managers and curators of dark tourism sites can effectively communicate the message of the site to tourists and visitors.

Debates should also be focused on the modalities of the visits, on the technologies of display implemented to remember and visualize the past, on the ethical issues related to leisure activities in sensitive locations.

Dark tourism is the type of tourism that should have highly educational role, while provoking endless discussions on how the difficult past could and should be presented to the visitors.

CONCLUSION

Dark tourism is a growing phenomenon internationally that has gathered significant attention on the part of the academic literature in the past decade. Including forms of cultural and historical commemoration, but also visits to sites of horror and violence, dark tourism is becoming an important source of income for some destinations.

The main motive for visiting all those dark memorials is to understand the causes and consequences of various events in order what to do that would never happen again, so find out what happened and understand why this has occurred. Strong motivation for visiting is also to commemorate the victims of a particular historically important area.

Also in Slovenia there are many dark stories (not only dedicated to war) and themes that can be developed into dark tourist products, as shown in the case of witches and witchcraft, which was prepared by the atmosphere of fear, envy and resentment. Usually an unfortunate happening, like hail, or illness, supposedly provoked by witches, or accusations among neighbours, initiated the charges of witchcraft. On most occasions people were not able to explain the reasons for disasters, thus witchcraft was a handy explanation. If prayers wouldn't help, nor amulets, nor church bells, only the stake remained.

The witch processes are classified among the dark phenomena in the history of mankind. These processes were nothing else but legal murders, the accused were burned for the actions which they could not have possibly done. In spite of numerous researches a satisfactory and final explanation for these wide-spread events has not been found. A reasonable explanation would be indeed quite hard to conceive. The idea of »evil«, which the

world is trying to eradicate by »fire«, is an old one, constantly reoccurring, and not limited to the past. The timeless conspiracy theory can be easily recognized in it, and whoever dares oppose is in danger of being quite quickly classified as one of the alleged conspirators. Thus the witch processes point out the possible connections with the contemporary history, and open the questions regarding the impulses within ourselves.

KEY TERMS AND DEFINITIONS

Cultural Heritage: The whole complex of distinctive material, spiritual and social achievements from the past that characterize a society or national identity.

Cultural Heritage Tourism: Visits by persons to experience, learn and appreciate the cultural legacy of people.

Dark Cultural Heritage: Cultural heritage that is associated with real and commodified sites of atrocity, death, disaster, human depravity, tragedy, human suffering, and sites of barbarism and genocide.

Dark Tourism: Special type of tourism, which involves visits to tourist attractions and destinations that are associated with death, suffering, disasters and tragedies venues.

Interpretation: All planned activities that communicate the importance and significance of what is seen and experienced by visitors.

Thanatourism: Travel to a location wholly, or partially, motivated by the desire for actual or symbolic encounters with death.

Tourism Product: Any product that is marketed by a country or an institution to attract the visitors and experience the said product.

H

Social Media as a Channel of Constructive Dialogue for Tourism Businesses

Marios D. Sotiriadis

University of South Africa (UNISA), South Africa

INTRODUCTION

Information and communication technologies (ICTs) are having a major impact on tourism in general. Ongoing developments in ICTs have significant changes in the way tourism-related information is distributed and on consumer behavior. The major impacts of the “digital revolution” on tourism have come through Social Media (SM) and mobile devices. According to the latest estimations the worldwide audience of SM has surpassed two billion users in 2015 (eMarketer, 2015). SM allow tourists to interact and share their views and experiences with potentially unrestricted virtual communities (Gretzel & Yoo, 2013; Leung et al., 2013; Sigala et al., 2012). This approach to meeting and communicating with people globally has revolutionized communications and consequently the marketing of tourism businesses (Munar & Jacobsen, 2014).

SM or Web 2.0 platforms include social networks (e.g. Facebook), blogs (e.g. Blogger), microblogs (e.g. Twitter), wikis (e.g. Wikipedia), content sharing platforms (e.g. AssociateContent.com) and text/audio/video sharing platforms (e.g. Flickr and YouTube). SM are presenting a host of new challenges as well as opportunities for tourism providers. One of their main functions is to establish an interactive channel of communication, which is mutually beneficial to both parties involved: it offers a medium for tourists to express their requirements, and gives tourism providers a tool to acquire customer feedback (Bilgihan et al., 2016). Whilst this represents a real challenge for tourism businesses, it also opens new channels of communication. It is therefore

imperative for tourism businesses to consider how SM is shaping business-to-consumer marketing communications and how may exploit their full potential (Benckendorff et al., 2014; Law et al., 2014; Sotiriadis & Van Zyl, 2013).

Within this context, the present article takes a marketing perspective to analyze the potential contribution of SM. The main aim is to examine and suggest the ways in which tourism businesses could take advantage of SM as a channel of constructive dialogue with customers. In sum, the paper suggests ways to take full advantage of SM in order to enhance listening to, and understanding of, their current and potential customers.

BACKGROUND AND LITERATURE REVIEW

The Internet has become the first-choice place for consumers to search for information on tourism destinations, as well as being the most important venue for marketing of tourism services (Benckendorff et al., 2014; Gretzel & Yoo, 2013; Law et al., 2014). The challenges and opportunities for tourism-related industries that arise from the digital environment are obvious in everyday business practice (Leung et al., 2013; Sigala et al., 2012).

During the last two decades scholars have shown an increasing interest in the growing role of SM in the tourism field (Law et al., 2014; Zeng & Gerritsen, 2014). The dominant topic investigated is the effectiveness of different digital marketing strategies and tools including SM (Law et al., 2014). The reason for this is that SM play a significant role in many aspects of tourism, especially

in decision-making behavior, tourism promotion and interaction with consumers (Bilgihan et al., 2016; Gretzel & Yoo, 2013; Law et al., 2014; Zeng & Gerritsen, 2014).

User-generated content (UGC) is one of the main activities of tourists on SM. They share their experiences, views and evaluations through online reviews. Examples of this behavior include posts, wikis, discussion forums, chats, tweets, podcasting, pins, and sharing of digital images, video and audio files (Munar & Jacobsen, 2014). The issue of implications of UGC has been examined by Ayeh et al. (2013), Boley et al. (2013), Wilson et al. (2012), Xiang and Gretzel (2010), and Ye et al. (2011). The topic of factors motivating tourists' involvement in SM was examined by Bronner and de Hoog (2011), and Munar and Jacobsen (2014). The study by Bilgihan et al (2016) explored the factors motivating consumers to share tourism information via SM. The study results show that the main factors of intention to share knowledge are belief in integrity and perceived ease of use. The issue of influence of SM on tourist behavior was examined by Parra-López et al. (2011) and Sotiriadis and Van Zyl (2013).

The present study is focusing on the impact of SM in the field of tourism business marketing and management. As argued by scholars, the changes of tourist behavior influence the approaches and tools that tourism businesses have to adopt and use in managing and marketing their offerings in the digital environment (Leung et al., 2013; Sigala, 2012; Sigala et al., 2012). Kim et al. (2015) suggested that online reviews in SM should be managed as a critical part of hotel marketing. Furthermore, tourism businesses make use of SM for various purposes, such as engagement, commitment, relationship building, and managing their reputation and brand (Dijkmans et al., 2015). The reason for the success of SM in business originates from the possibility to manage relationships with customers in a customized way (Calefato et al., 2015).

Literature also suggested that SM are an effective marketing channel that can be wisely used in integrated marketing communications of tourism services (see, for instance, Oz, 2015; Sotiriadis & Van Zyl, 2013). Additionally, SM can be used by tourism businesses to support and enhance knowledge management (KM) activities, as suggested by Sigala (2011), and Sigala and Chalkiti (2014). The mass collaboration and communication functionalities of the SM can support and enhance conversational, participatory and collaborative KM processes; i.e. searching, sharing and creating information and intelligence. Examples of internal KM processes include searching, storing and collecting information, and practices of organisational learning and internal social bonding. External KM processes include sharing, discussing and creating knowledge with others (Sigala & Chalkiti, 2014). Finally, the study by Xiang et al. (2015) pointed out the tremendous growth of SM and UGC on the Internet and demonstrated the utility of big data analytics to better understand important hospitality business issues.

The above literature review indicates that the field of SM is a challenging topic. As can be seen, the crucial issues are to adopt the appropriate approach and to use SM in the field of tourism efficiently in order to exploit the full potential of this social phenomenon. Savvy tourists are now 'unbundling' the whole planning, booking and sharing of their experiences (Morrison, 2013). SM are one of the tools at their disposal and they are taking full advantage of it.

The interaction of the main challenges in the tourism market with the digital environment and the impressive adoption and use of SM clearly indicates that tourism providers need to adopt new approaches in the field of communications, such as developing a multi-channel approach to communications, embracing the influence of SM, and engaging customers in a mutually beneficial dialogue. This article argues that SM could have a stronger contribution in the fields of service experience improvement and innovation in tourism.

SOCIAL MEDIA AND TOURISM SERVICES

The present article suggests that tourism providers have to examine the ways in which tourists are using SM in order to better communicate and interact with them. SM have become important social platforms for online communications giving people the opportunity to find and then communicate to others with similar interests (Ayeh et al., 2013). SM are powerful platforms that allow consumers to collaborate and contribute to developing, extending, rating, and commenting on tourism experiences. They have been recognized as innovative knowledge sharing networks by enabling consumers to connect, share, and interact with others (Oz, 2015). That is the reason why SM, as knowledge sharing platforms, are gaining attention for the tourism industry.

SM sharing and adoption is growing globally, according to a report by eMarketer, the number of SM users across the globe exceeds 2 billion users and more than 28% of people worldwide used SM regularly in 2015 (eMarketer, 2015). Business reports indicate that SM are well established as key sources of information for tourists before, during and after their trips. SM now play a major role in travel planning for many travelers around the world. These estimations are confirmed by the findings of Tripbarometer survey conducted by Ipsos and TripAdvisor (TripAdvisor, 2014). As for the reviews, it seems that customer feedback plays a key role in the travel cycle: 89% of global tourists say reviews are influential when choosing where to book. Global tourists' decisions of where to travel are based 65% on online travel reviews and 48% on personal recommendations.

The Global Trends Report (WTM, 2015) also highlighted the emerging trends in the global tourism industry. The key findings of this report include the following: (i) Mobile technology is currently transforming the tourism landscape in terms of bookings, customer service and consumer behavior; mobile bookings are expected to reach 35% of online tourism bookings by 2018;

and (ii) Destination services, personalization, mobile bookings and peer-to-peer platforms and services are expected to be the main disruptive forces in the tourism industry over the next five years. These developments represent a challenge for tourism providers which will need to build a flexible technological architecture to follow their customers from one device to another.

Given the fast-growing SM usage trend worldwide, tourism providers are embracing SM more than ever as part of their marketing strategies. SM strategies of tourism providers have been robust in recent years, and nearly all major brands and global chains are now present on SM platforms. However, those companies that have succeeded the most on SM are the ones using content drawn from their customers' and potential customers' behavior online (WTM, 2015). Within the context of a fragmenting marketplace, the crucial point is to make SM more successful in keeping people engaged (Bilgihan et al., 2016; Law et al., 2014).

Let us consider the example of Twitter that is one of the best-known SM and micro-blogs in Europe and America. This SM is a real-time information network, powered by people in nearly every country in the world in six languages, and is continually expanding (Twitter, 2015). Twitter is now one of the world's most popular micro-blogs and functions as a source of entertainment and leisure (Morrison, 2013). Many hospitality businesses are using Twitter to build their brand and connect more personally with their customers (Chan & Guillet, 2011). Some recent facts and figures to note about Twitter are (Bullas, 2015): In 2015 Twitter has 284 million active users at last count, 88% of Twitter users are on mobile, and they post 500 million tweets per day. The information that spreads through Twitter can help tourists make better choices and decisions.

A study by Sotiriadis and Van Zyl (2013) explored the use of online reviews by Twitter users and followers in their decision-making behavior about tourism services purchases and the factors influencing the use of information retrieved from this micro-blog. The study findings indicate that

three factors are very influential regarding the use of information about tourism services retrieved from Twitter, namely: (i) credibility of Twitter followers/users; (ii) degree of involvement/posting; and (iii) expertise and know-how of Twitter users/followers. This knowledge is very useful in tourism marketing. Tourism businesses are increasingly adopting SM marketing, which consists mainly of exploring opportunities provided by SM and implementing actions to respond positively to online users/members' reviews, suggestions and experience sharing. These valuable sources of feedback provide information that enhances customer relationships, determining their needs and requirements and contributes to improving service quality (Sotiriadis & Van Zyl, 2015).

It is believed that the true value of SM in general lies in the ability to really listen and respond to, to efficiently interact with customers. SM give tourism marketers access to a targeted audience and relevant conversations. How can SM be used by tourism providers? The next section deals with this question.

SUGGESTIONS AND RECOMMENDATIONS: SOCIAL MEDIA AS A CHANNEL OF CONSTRUCTIVE DIALOGUE BETWEEN TOURISM BUSINESSES AND CUSTOMERS

Most tourism businesses are now heavily engaged in using SM platforms to distribute information and communicate with others. The major activities of tourism providers in using SM include collecting UGC, displaying photography and videos, distributing topical news stories, emphasizing current events, encouraging electronic Word-of-Mouth (eWOM) recommendations, and getting feedback (Morrison, 2013).

This article focuses on the appropriate approach to, and adequate use of SM by tourism providers based on two key concepts, namely engagement and interaction/dialogue. Tourism businesses

should approach SM as a means of interactive communication with customers and a tool for customer feedback. Customer feedback is "the transmission of negative information (complaints) or positive information (compliments) to providers about the services used" (Saha & Theingi, 2009, p. 354). Hjalager and Nordin (2011) argue that the active exchange of ideas and resources with customers may facilitate and benefit the learning process, enhance innovation capacities and ultimately increase the competitiveness of companies. Customers could influence tourism providers to improve the experience service quality and to affect or improve a company's innovation performance. Hence, it is suggested that these are the two fields in which SM might make a contribution: (i) experience quality/performance adjustments and (ii) service innovation.

1. SM: a Medium of Feedback for Performance Adjustments and Improvement

The practice of listening to and learning from the customers when delivering a service is extensively used in tourism but not in a systematic way (Sigala et al., 2012). Posts and comments on SM provide input that can be useful for tourism providers in identifying areas in which adjustments of performance are required, product innovation might be developed or new offerings introduced. In a service experience, customers participate in the process of providing this experience and there is high customer contact throughout the service process. That is the reason why the customers' perceptions of the company and of its offerings must be managed well.

It is suggested that tourism providers should use SM a channel for listening to and for interactive communication with customers, by implementing specific strategies, such as (i) create a virtual environment that builds a virtual community by engaging tourists to share their knowledge; (ii) design SM communications to encourage tourists to share the nature of their experiences both during and after their experiences (Bilgihan et al., 2016; Kim et al. 2015; Xie & Zhang, 2014).

Attempts to interpret customer reactions in external and internal contexts are valid enough as a basis for everyday managerial adjustments. The importance of monitoring information on customer satisfaction as a measure of system performance, and the significance of people involvement and continual improvement in the service process, is well documented in the literature (see, for instance, Fitzsimmons & Fitzsimmons, 2008). Service management must enable the management to explore customers' ideas and suggestions for improvements. This approach enhances and supports the continual improvement of processes and, consequently improves customer satisfaction.

Data-mining from SM should be implementing in better understanding of consumer behavior, choices, concerns and determinants. Literature suggests some ways of effectively leveraging of UGC across SM platforms by using the adequate techniques / tools (see, for instance, Capriello et al., 2013; García-Pablos et al., 2016; Ghose et al., 2012; Xiang et al., 2015). Methods include approaches for mining consumer sentiment, such as manual content coding, corpus-based semantic method, and stance-shift analysis. These methods vary greatly in both process and output; however, from a methodological viewpoint, all three methods produce reliable results. As for the tools, they include machine learning techniques, text analysis, crowdsourcing, image classification, social geotagging, human annotations, and geomapping, as well as Natural Language Processing (NLP) tools to automatically process and manage textual customer reviews (e.g. to perform sentiment analysis).

Thus, listening carefully to customers can be a goldmine of information that can lead to improvements in products, services and processes, as suggested by Hjalager and Nordin (2011). Therefore, tourism providers might benefit from feedback and input coming from SM users.

2. SM: Knowledge Source for Customer-Driven Innovation

It is suggested that tourists may provide companies with input and knowledge that could be used to improve processes and develop new concepts. In simple terms, innovation means the introduction of new products/services, new production processes, managerial revisions and communication changes. Hjalager (2011, p. 127) defines innovation as “the creation of better or more effective products, processes, services, technologies, or ideas that are accepted by society, markets, and government”.

Listening to customers and relationships with them has always played a central role in tourism. However, the involvement of customers as informants often seems to be coincidental and unsystematic, and may also be contested. Hjalager and Nordin (2011) outline a series of methodologies/ approaches to customer-driven innovation. One of these approaches is blog mining. In fact, tourism blogging is not a new form of review. Interactive travel forums such as TripAdvisor.com and travelblog.org encourage tourists to recommend facilities to others (Lee et al., 2011).

The study by Volo (2010) assessed the value of tourists' blogs as a research data source by using them to evaluate the tourist experience and to assess their influence on the decision-making process of prospective tourists. The methods implemented were textual and image content analysis. On the whole, blogs constitute an immense resource providing insights that may be fed into innovation processes. Like other knowledge sources, blogging has its obvious drawbacks in terms of fostering innovation in tourism (Hjalager & Nordin, 2011).

Let us give some practical examples of performance adjustments and improvement resulting from customer input and knowledge that lead to new/better products and services in the field of wellness tourism and spas (Sotiriadis et al., 2016): (i) improvement of elements of architecture and design to create harmony and balance within the space; pairing built environment, treatment and adequate design allowing proper satisfaction of all senses; (ii) redesign of functionality and décor to add a sense of relaxation, health and

Table 1. Summary: Suggestions for potential contribution and uses of SM

Issues	Elements
Areas of potential contribution	Listening carefully to and learn from customers can be a goldmine of input and knowledge that could influence tourism providers (i) to improve the experience service quality, and (ii) to improve their innovation performance.
Approach and Policy	Integrated communications with customers: (i) Develop a multi-channel approach to communications; and (ii) SM as channel for interactive communication.
Strategies in acquiring customer feedback	- Engagement of customers in a mutually beneficial dialogue - Enhance participation and intention to share input and feedback through the use of SM. - Listening to customers and responding to tourists' comments and feedback - Use SM as a medium and source of feedback for performance improvement - Use SM as knowledge source for customer-driven innovation.
Operational management actions (Meaning implementing actions to:)	- Encourage tourists to relate effective service stories online. - Respond positively (taking advantage of positive postings and addressing negative comments) to online users' reviews, suggestions and experience sharing. - Analyze and interpret customer reactions for operational management adjustments. - Monitor customer feedback - Monitor customer satisfaction as a measure of system performance. - Involve customers systematically as informants in a process of continuous service improvement. - Focus more on lurking: Monitoring online reviews and experience sharing to understand tourists' needs and experiences - Use SM in listening on the online conversation; - Instigate engagement behavior / Use social gratifications to enhance tourists' participation and engagement on provider's website - Employ systematic approaches to exploit ideas and inspiration from customers - Mine blogs as a resource providing input into innovation processes - Use ideas and suggestions from customers in improving company's innovation performance.

Source: Adapted from Sotiriadis and Van Zyl, 2015, p. 173.

cleanliness to customers; more particularly offer aesthetic configuration, comfort and space; (iii) reprocessing/adequate design of treatments using innovative methods to rejuvenate body, soul and spirit; (iv) moving from a basic package of treatments to specialization, customized/thematic and signature treatments (e.g. signature chocolate treatments and spa packages); (v) offering new experience opportunities for a variety of treatments and adequate products (e.g. anti-ageing and result-oriented treatments); and (vi) use of SM platforms in communicating the highlight offers to the target market segments.

SM constitute electronic platforms for tourism businesses to interact with existing and potential tourists (Sotiriadis & Van Zyl, 2015). The following table is a summary of suggestions about the potential contribution and possible uses of SM by tourism providers. To benefit, they need to identify specific areas of contribution and develop effective strategies to optimize returns.

As was stressed earlier, customer knowledge and input should be seen as an opportunity, not a threat. It is quite clear that listening to tourists is vital to understanding and responding to their needs. It is worth pointing out that influencing the participation and the intention to share input and feedback through the use of SM requires tourism providers to influence consumers' beliefs and to differentiate themselves from their competitors. Scholars suggest developing SM platform that provides functional and practical benefits (Bilgihan et al., 2016).

FUTURE RESEARCH DIRECTIONS

This article provides some guidance on an approach to and possible uses of SM by tourism providers. It is believed that there is a need for more in-depth conceptual approaches and empirical investigation and studies to advance research

and knowledge in this area. Some suggestions for future research include exploring issues such as (i) the degree to which tourists are willing to participate in customer feedback and customer-driven innovation activities; and (ii) the feasibility of different SM within a general approach of interactive dialogue with customers. Another possible direction for future research is to examine the similarities and differences in engagement behavior of tourists using general SM and tourism-specific SM (for instance, Travelblog). Another research path could be the comparative analysis of micro-blog and tourism-related SM, such as interactive travel forums (e.g. TripAdvisor), and their use by both interest groups: tourists for inspiration and information purposes and tourism providers as complementary tools for marketing intelligence and innovation purposes.

CONCLUSION

For tourists, the Internet and SM have become an entertaining venue to gain knowledge and get first-hand reports of experiences. SM have opened up a new world of dialogue among people, including conversations about tourism services and destinations since they facilitate direct interactions between suppliers and tourists. It is therefore imperative for tourism providers to understand how they can be used for managerial and marketing purposes. By using SM effectively, tourism providers are communicating directly and efficiently with their current and potential customers.

Markets become conversations and tourism providers must engage others to have good conversations about their offerings. This involves marketing challenges for tourism businesses, mainly (i) elaborate and implement strategies to use these channels for dialogue and interaction purposes with consumers; and (ii) convince tourists to share their experience and knowledge via SM. Tourism providers who manage to create an

SM environment that builds a virtual community by engaging tourists to share their knowledge and insights will be more successful.

This article suggested two specific uses of SM by tourism providers, namely as a medium of feedback for performance improvements, and as a knowledge source for customer-driven innovation. It also pointed out some appropriate methods and suitable techniques/tools of effectively leveraging of UGC (reviews and experience sharing) across SM platforms. The latter must be approached and used as a tool and a resource to harvest valuable ideas and inspiration from customers.

However, tourism marketers must be aware of the limitations of every tool and method. How can tourism providers use SM and knowledge and input from customers? In practice, it will often be necessary to combine customers' inputs with other types of knowledge acquisition, as well as with other methods and tools. Customer feedback must be regarded as food for marketing, although it is usually a difficult management task to draw conclusions and come up with solutions. Therefore, this tool and its uses should be part of a marketing strategy and innovation management. In other words, the effective approach is to transform SM into a website dedicated to feedback; that is, websites allowing users to post, read, review, discuss and share experiences and opinions. Within a digital environment, the approach to marketing must be interactive. Tourism providers need to adopt a multi-channel approach to communications. The crucial issue is to communicate efficiently with tourists; a successful digital strategy will provide opportunities for suggestions and feedback.

Finally, it is worth emphasizing that SM are not panaceas; they are additional tools in the marketing toolbox. In order to improve their efficiency and effectiveness, SM must fit into integrated marketing communications plans and used as a channel for interactive communications, with the main aim to convert them in a medium for constructive dialogue that is mutually beneficial.

KEY TERMS AND DEFINITIONS

Blogs: Blogs are websites on which people (bloggers) keep logs, share personal experiences and insights in a particular area, and interact with readers through the posting of comments.

Customer Feedback: The positive or negative information transmitted by customers to busi-

nesses about the quality of services provided and the degree of satisfaction.

Innovation: The introduction of new products/services or new production processes. It is defined as the creation of better or more effective products, processes, services or ideas that are accepted by the market.

Social Media: Any tool or service that uses the Internet to facilitate conversations; a group of internet-based applications that enable internet users from all over the world to interact, communicate and share ideas, experiences and information.

Social Media Marketing: A set of marketing techniques that use SM to create increases in brand awareness, achieve increased visitation and enable interaction, communication and collaboration of user-generated content.

Tourism Providers: All businesses offering tourism services and experiences to consumers when the latter are travelling and performing tourism activities. These businesses include transport companies, hospitality companies, travel agents and tour operators and other tourism-related companies directly involved in servicing tourists' needs.

Web 2.0: Describes websites that emphasize user-generated content, usability, and interoperability. A Web 2.0 site may allow users to interact and collaborate with each other in a SM dialogue as creators of user-generated content in a virtual community.

Usability Evaluation of Tourism Icons in India

H

Rajshree Tushar Akolkar

Zeal College of Engineering and Research, India

Ganesh D. Bhutkar

Vishwakarma Institute of Technology, India

INTRODUCTION

In India, there are twenty nine states and seven union territories and most of them have their official tourism websites. These websites are designed to provide relevant tourism information and services to the Public and visiting Tourists, who are Indian Citizens, Non-Resident Indians (NRI) or Foreigners. There are unique tourism icons used by these Indian tourism websites, which represent a diversified culture of the respective state of India. There are three major types of icons viz. simple icons, indices and symbols. An icon is a visual sign that looks like what it means. An index indicates about a particular object or process through indirect means. A symbol is a sign which is used for representation of objects or process through convention or standard (Agrawal & Bhutkar, 2012, 2015; Bhutkar et al., 2011; Cumbria, 2015; “Horton”, 1994; Specht, 2014; Kalsi et al., 2009; Shah, 2007; Withrow et al., 2000). The examples of icon, index and symbol in e-Governance websites are depicted in Table 1. An icon showing a house represents housing. An index for education is represented using a graduation cap with rolled degree and red ribbon, which is an indirect representation of education. A symbol for differently-abled services is depicted by a person in sitting position on chair-like object. All the icons in Table 1 are referred from a section – ‘Topic’ on Indian e-Governance Portal (“India Web Portal”, 2016).

The tourism icons used in these websites are of the type – index and each of these icons indicates about state tourism through indirect mean representing regional or cultural aspect(s) of the respective state of India (Bhutkar et al., 2011; Kergosien, 1991). In this chapter, the tourism icons available with these state tourism websites are studied and evaluated to propose a comprehensive methodology of icon evaluation.

Characteristics of Icons

The icons have about 40 characteristics representing several aspects incorporated in them (“Horton”, 1994; Specht, 2014). These icon characteristics include major characteristics such as –

- **Functional Analogy:** If you can’t show the object itself, you can show the object that performs an analogous function in more familiar area.
- **Animal Use:** Animals or birds are used as symbols.

Table 1. Examples icon, index and symbol in e-governance websites

Icon	Index	Symbol
		

- **Overlapping:** Allowing one object to block the view of another for conveying the proximity.
- **Size:** Size is a dimension or magnitude of any object.
- **Shape:** Shape is an outline of any object.
- **Clarity:** Clarity is defined as a clear, understandable, informative and easy association with the message.
- **Universal:** Globally used.
- **Labels Off:** Labels are not displayed or required (If symbol is not obvious or known to all readers then it must be labeled).
- **Functional Analogy:** If you can't show the object itself, you can show the object that performs an analogous function in more familiar area.
- **Color Indicator:** In color indication, each color denoted by background, border or text may have a different meaning.
- **Animal Use:** Animals or birds are used as symbols.
- **Overlapping:** Allowing one object to block the view of another for conveying the proximity.
- **Size:** Size is a dimension or magnitude of any object.
- **Shape:** Shape is an outline of any object.
- **Clarity:** Clarity is defined as a clear, understandable, informative and easy association with the message.

The icon characteristics are divided into two parts. A first part contains primary characteristics, which are required characteristics observed in most of the icons. The tourism icons have three required characteristics such as labels off, clarity and functional analogy. These characteristics are observed in most of the tourism icons. For example, a tourism icon for a state of 'Himachal Pradesh' is shown in Figure 1, which consists of Deodar Trees, Sun, Moon, Caves and Hills. This index does not have any label; which is a 'labels off' characteristics. This index is easily understandable and 'Clear'. It has a 'Functional

Figure 1. Tourism icon for the state of 'Himachal Pradesh'

analogy' in the form of natural entities such as Sun, Moon, Caves, Hills and Deodar trees representing a state of 'Himachal Pradesh' and natural life in Himalayan mountain ranges.

Ten tourism icons have been selected satisfying primary characteristics and are depicted in Table 2. The other part has secondary characteristics,

Table 2. Icons from state e-governance websites of India list of selected tourism

Icon	Icon Represented In State	Icon	Icon Represented In State
	Bihar		Nagaland
	Gujarat		Kerala
	Haryana		Rajasthan
	Himachal Pradesh		Jammu and Kashmir
	Sikkim		Tamil Nadu

which are optional and can be observed in a few of the icons. The tourism icons have many secondary characteristics such as animal use, overlapping, color indicator, shape and structural analogy. For example, a tourism icon for state of Gujarat has the 'Lion Face' which is the unique species ('animal use') found only in 'Gir Forest' in Gujarat. A characteristic like 'Overlapping' is present in a tourism icon for state of 'Jammu & Kashmir'. This index has the 'Shikara', which is a type of wooden boat normally found in 'Dal Lake', mountains and lake. A 'Color indicator' conveys the purpose (Specht, 2014). Many icons have used a green color to indicate trees or vegetation around, like tourism icons for 'Himachal Pradesh', 'Kerala' and 'Bihar' show tree(s) in green color.

Research Questions

This book chapter is an attempt to investigate two major research questions related with icon evaluation as follows:

1. Are the icons from tourism websites easily understandable to Public / Citizens?
2. How to evaluate and validate icons on tourism websites satisfactorily to fulfill their role in interaction with Public / Citizens?

BACKGROUND

An e-Governance is a big challenge and far big opportunity to bring services to all the Citizens for India, which is second-most populous and the largest democratic nation in the World. The most significant characteristic of any successful e-Governance website is its quality and accessibility (Agrawal & Bhutkar, 2015). The issue (appearance, cost and time) of integration of legacy systems also comes into the scene. The presence of e-Governance icons in general, makes these user interfaces and websites more user-friendly and easy to use in Human Computer Interaction (HCI) or usability perspective. Such iconic user

interfaces may be displayed for interactive usage to the users, who may be from weaker socio-economic and educational background. The appropriateness of these icons can be identified by usability evaluation of their designs. The user participation is always vital in such evaluations as e-Governance websites are used by Public i. e. people representing several categories such as Government Servants, Public Sector Employees, Private Sector Employees, Social Workers, Politicians, Academicians, Students as well as Foreign Nationals. The major usability issues with e-Governance icons include legibility, size and position of icons (Bhutkar et al., 2011). Icon legibility and size of most icons can be important issues during icon selection. These icons should be visible throughout the web pages visited for the necessary operations, which can be observed during the process of lexical analysis. These issues put icons at center of attention during usability research.

LITERATURE SURVEY ABOUT E-GOVERNANCE AND ICONS

Most of the papers studied in the literature survey section have tried to evaluate the e-Governance websites on the basis of maximum possible parameters pertaining to an aspect of visual design.

A research by Katre et al. (2004 & 2011) highlights the minimum essential parameters belonging to 8 different aspects of the state government websites in India. The overall result of the evaluation is considered as integrated feedback of Usefulness and Usability of the state web portal. The evaluation is only in terms of the presence or absence of the particular factors or applicability of the given parameter. The presence of proper visual design is recorded as (1) whereas its absence or poor design is recorded as (0). They have not rated the websites in terms of which one has better or worst visual design. The following are the usability aspects for e-Governance: Accessibility, Navigation, Visual Design, Readability, Informa-

tion Content, Textual Elements and Interactivity (Katre & Gupta, 2011).

Shah (2007) has discussed about what is e-Governance and structure of e-Governance in India. This study has analyzed the governance issues and challenges for the country. Withrow et al. (2000) has undergone a study of comparative usability evaluation for an e-Governance website. These studies have been instrumental in development of in-depth understanding about how to work with e-Governance websites.

Horton (1994) has discussed in his book - "The Icon" about fundamental of icons such as icon style, appearance, fitting, design and evaluation methods. It has described various components of icons viz. border, background, label, size, shape, synecdoche, clarity etc. This study has applied the appropriate component-based criteria learned for selecting suitable icons from e-Governance website for further semiotic analysis.

Bhutkar et al. (2011) has used the semiotic analysis combined with usability and ergonomic testing for evaluation of icons in medical user interfaces. In this paper, Usability Evaluation Methods (UEM) such as usability testing, user survey, lexical analysis, semiotic analysis and long distance visibility testing are used to evaluate the selected icons. This study have used lexical breakup for generating a data required for classification of icons related with medical user interfaces.

International language of ISO Graphical Symbols (2013) has defined, internationally accepted requirements for designs, colors, contents and shape of graphical symbols. The standardized colors and basic shapes for icons are important in helping the different types of signs, and messages they convey. This study has helped in understanding importance of identification as well as location of the icons.

Francesco (2011) has discussed about qualification of the tourist destination being worthy and the colors employed to indicate trails for outdoor activities. This study has been used in tourist world for recognizable and memorable iconography of the object and the use of related

images. It has been useful in identifying and selecting the appropriate tourism icons during this research work. Cumbria Country Council (2015) has explained benefits of symbols in simplifying the sign contents, size, use of colors, basic shapes to design and recognizing the icons using signs and symbols. It has integrated a tourism signage with strategic signage for towns and villages. This study has been beneficial in understanding and selecting the characteristics of icons.

There are many studies which elaborate on classifications of icons. Kergosien (1991) has discussed the semiotic analysis of medical imaging. As per this study, there are three types of signs viz. icon, index and symbol. Poovaiah (1995) has stated that the symbol design is governed by visual language which has various message representations such as - iconic, indexical and symbolic representations. This study is also useful for the classification of icons into icon, index and symbol.

RESEARCH METHODOLOGY

Following are the major steps involved in research work related with usability evaluation of tourism icons:

- Selection of Tourism Icons
- Usability Evaluation Methods (UEM)
 - Using Expert-based UEMs
 - Using User-based UEMs

These steps are discussed in details in this section.

Selection of Tourism Icons

In India, twenty nine states and seven union territories have their official tourism website. There is a distinct tourism icon representing each of these states or territories in India. These icons are extensively used by respective state tourism departments with their e-Governance Websites. Ten icons are selected based on their primary as well

as secondary characteristics as discussed earlier. The legibility of icons has been also a vital issue during icon selection. The selected ten icons are depicted in Table 2. The primary characteristics considered are labels off, clarity and functional analogy. These icons also have secondary characteristics such as shape, structural analogy, animal use, overlapping, interact icon and color indicator.

Most of the icons are rectangular in shape except the icons representing Kerala and Tamil Nadu. An icon of Himachal Pradesh has used background structure whereas Nagaland and Rajasthan have used hut and train structures respectively. The icons of Gujarat and Haryana have used as animals/birds and strips. An overlapping means a use of many related objects, which has a strong relation (“Horton”, 1994). The icon designs of Himachal Pradesh and Kerala depict a characteristic of overlapping.

Usability Evaluation of Tourism Icons

Usability evaluation of icons is carried out using selected UEMs. These methods include both expert-based UEMs as well as User-based UEMs (Agrawal & Bhutkar, 2012, 2015). These methods are discussed ahead.

Expert-Based UEMs

An expert-based UEM is any UEM, which involves usability expert examining the application or product and estimating its likely usability for a given user population. In expert-based methods, the users may not be employed and the basis for the evaluation lies in the interpretation and judgment of the expert evaluator. There is a considerable interest in such methods since they can produce results faster and are presumably cheaper than user-based UEMs. Two major expert-based UEMs used for usability evaluation of tourism icons are lexical analysis and semiotic analysis, which are discussed in next section.

Lexical Analysis

Linguistics has a term - ‘Lexical Analysis’ which is a process of converting a sequence of characters into a sequence of tokens. This study has used the concept for analysis of icons and performed a lexical breakup of icons during analysis. A lexical analysis has helped in classification of icons into mainly three categories: icon, index and symbol. A Table 3 has depicted the lexical breakup and categories of 10 tourism icons based on lexical analysis. This table shows that all tourism icons have indexical features in them.

Semiotic Analysis

A semiotics is a study of cultural sign processes, analogy, signification, communication, signs and symbols. Signs and relations are two key notions in semiotic analysis. An arbitrary and temporary separation is made between content and form to provide enough attention on the system of signs (“Cumbria County Council”, 2015; Francesco, 2011). Thus, a semiotic analysis is concerned with meaning, which came from relationships - in particular, the relationship among signs (“The International Language of ISO Graphical Symbols”, 2013). A semiotic analysis is closely related to the field of linguistics (De Souza, 2006). It is based on three major dimensions - namely semantics, syntactic and pragmatics. Semantics deals with a relationship of icon to its meaning. Syntactic deals with a relationship of icon to its form. Pragmatics deals with a relationship of icon to its users. The icons can be evaluated with these three dimensions by answering related questions.

Following are the standard questions for Semantic, Syntactic and Pragmatic dimensions (Agrawal & Bhutkar, 2012, 2015):

Questions for Semantic Dimension

- How well does the icon represent the message?

Table 3. Lexical breakups and classification of tourism icons based on lexical analysis

Sr. No	Tourism Icon (Index)	State associated with Represented Icon	Lexical Breakup	Remark
1		Bihar	Peepal (Bodhi) Tree	Peepal (Bodhi) tree is the tree under which Goutama Buddha attained his enlightenment. (ToI)
2		Gujarat	Lion Face + Border	Lion is unique species found only Gir Forest, Gujarat and no-where-else in Asia. (email)
3		Haryana	Peacock Animal + Back Ground	Peacocks are found in almost everywhere in Haryana. Suraj Kund in Lokarpur (Haryana) is a tourist place, which looks like a dancing peacock (Website) .
4		Himachal Pradesh	Deodar Trees + Hills + Moon + Sun + Cave	Deodar Tree – State Tree Hills – Roads are major mode of Transport and it is hilly Sun and Moon – Climate varies from hot and sub-humid to cold Cave – Rock cut caves (Website)
5		Sikkim	Tashi Tegye	The eight signs are called tashi tegye in taibetan. These auspicious signs are intimate with life and teaching of Buddha. (Website)
6		Nagaland	Ne Hut	A hut represents cottage industry such as spinning, weaving, woodwork, pottery and cane work. (Website)
7		Kerala	Coconut Tree + Mountain	Coconut tree
8		Rajasthan	Rath (Chariot) + Back Ground	The Royal Rajasthan on Wheels is a luxury tourist train run by Indian Railways, which follows a route through Rajasthan. (Website)
9		Jammu and Kashmir	Hills + House Boat + Back Ground	Shikara is a type of wooden boat which is normally found in Jammu and Kashmir, which is a hilly region. Shikaras and houseboats are used for transportation, fishing and seaweed harvesting. (email)
10		Tamil Nadu	Umbrella	Artistic work selected by TTDC Ltd. (TTDC Website an email)

- Has the icon already been accepted?
- Do people fail to understand the message that the icon denotes?

Questions for Syntactic Dimension

- How does the icon look?
- How well do the parts of icon relate to each other?
- Is the construction of the icon consistent in its use of orientation, format, scale, color and texture?

Questions for Pragmatic Dimension

- Can a person see the icon?
- What is the preferred position of icon?
- Does the icon remain visible throughout the operation?

For such categorical analysis, questionnaire method was used during the process of related user-based evaluation. These evaluations involving users are discussed in next section.

User-Based UEMs

Usability testing is used as User-based UEM in evaluation of icons. It involves a sample of users performing a set of pre-determined process or tasks. An aim of such testing is to examine the extent to which the application or product supports the intended users in their work (Agrawal & Bhutkar, 2012). Thus, users are asked to perform a set of tasks with the application or product. Depending on the primary focus of the evaluator, the users' success at completing the tasks and their performance may be recorded. After the tasks are completed, users are often asked to provide data on likes and dislikes through a survey or interview.

Following user-based methods are applied during usability evaluation of tourism icons:

1. User Survey
2. Test without Context
3. Test with Context

User Survey

User survey is a non-experimental descriptive research method. Surveys can be useful when a researcher needs to collect data on phenomena that cannot be directly observed (Kothari, 2004). Surveys are used extensively in library and information science to assess attitudes and characteristics of a wide range of subjects, from the quality of user-system interfaces to library user reading habits. A role was class of user such as primary or secondary user. The user preferences mainly included user's opinion about icons in terms of scale of goodness (1-5) as well as specific suggestions for improvement (Johns, 2010).

About 200 users were contacted in person or through email, but only 81 users responded with all three questionnaires answered completely. These 81 users participated in the usability testing as well as related user survey. These users are selected through convenient sampling method (Bhutkar et al., 2011; Kothari, 2004). Most of these users often deal with e-Governance Websites. The members such as Academicians, Social Workers and Students had responded in person and others had responded through an email. The frequency of users' responded under user type survey is listed in Table 4.

Table 4. User type wise frequency of e-governance users

User Type	Frequency
Central Government Servant	05
State Government Servant	02
Public Sector Employee	10
Private Sector Employee	23
Academician	11
Student	19
Politician	02
Social Worker	04
NGO Member	03
Others	02
Total	81

User survey mainly involved collection of data about user profiles and their preferences. User profile was an important document in evaluation of icons. It had vital information about e-Governance website users such as user type, age, state, contact, language skills etc. The state wise representation of users is shown in Table 5.

Table 6 shows the age range of users' and age wise frequency of users. In other state category of state wise users are from Uttarakhand, Uttar Pradesh, Andhra Pradesh, Karnataka, Jharkhand and Chandigarh as well as from a few countries such as USA, Saudi Arabia and Switzerland.

User Profiles

Following are the observations made based on study of user profiles of participant e-Governance users during usability testing and user survey.

Table 5. State wise frequency of e-governance users

States		Frequency
Andhra Pardesh		2
Bihar		2
Gujarat		3
Haryana		4
Himachal Pradesh		3
Jammu & Kashmir		1
Jharkhand		1
Kerala		1
Karnataka		2
Maharashtra		38
Orissa		2
Rajasthan		3
Tamil Nadu		4
Uttar Pradesh		5
Uttarakhand		2
West Bengal		2
Others	USA	2
	Saudi Arabia	1
	Switzerland	1
Total		81

- Many users were personally interviewed in Maharashtra, India. All Central Government Servants, State Government Servants, Public Sector Employees, Private Sector Employees, Academicians, Politicians and Non-Government Organization (NGO) Members responded through an email. Among Private Sector Employees, two users were working in USA, one worked in Saudi Arabia and one worked in Switzerland. Three users working in USA and Switzerland were NRIs and a user from Saudi Arabia was Foreigner.
- Participant users had proficiency in two to four languages. These languages mainly include English and Indian languages such as Assamese, Bengali, Gujarati, Hindi, Kannada, Kashmiri, Marathi, Nepali, Oriya, and Telugu. One user even had good knowledge of Arabic.
- The frequency of users calculated as User Type wise shown in Table 4, State wise shown in Table 5 and by Age wise shown in Table 6.

The actual User Profile entered by the user is shown in Figure 2.

Test Without Context

In this user-based test, only one icon is displayed at a time without any context or associated proposition like title, other icon or interface screen, as

Table 6. Age wise Frequency of e-Governance Users

Age Range	Frequence
Below 20	12
21-35	44
36-50	17
51-60	6
Above 60	2
Total	81

Figure 2. User Profiles

Icons from Indian e-Governance Website: User Profile		
No	Personal Information	Details

15*	User Type:	Central Government Servant / State Government Servant / Public Sector Employee / Private Sector Employee / Academician / Student / Politician / Social Worker / NGO Member / Other (specify)
16	Signature:	[Signature]
17	Date:	20/04/2012

(* The items in bold will be filled by Interviewee (Researcher))

shown in Figure 3. Then, users are asked to evaluate it based on a related questionnaire.

The questionnaire for Test without Context in semiotic analysis (AIGA, 1981) is provided below:

Questionnaire for this test had following questions:

1. What does the icon represent?

Figure 3. Icon for Gujarat tourism using test without context

Icon No. 2

2. What are operations indicated by the icon?
3. Does the logical structure among objects shown, help to find the information one is looking for?
4. Any other suggestions/observations (e.g. color, color code, orientation etc.)?

Test With Context

In this user-based test, each icon is displayed along with context i. e. with related interface in part or completely with associated propositions, as shown in Figure 4. Then, users are asked to evaluate it based on a related questionnaire.

The questionnaire for Test with Context in semiotic analysis (AIGA, 1981) is provided below:

Questionnaire for this test had following questions:

1. What does the icon represent?
2. What are operations indicated by the icon?

Figure 4. Icon for Gujarat tourism using test with context

3. Does the logical structure among objects shown, help to find the information one is looking for?
 4. Is a size of the icon appropriate?
 5. Is a location of the icon proper? If no, then – What is the preferred location?
 6. Should the icon be visible throughout the operation?
 7. Scale of Goodness (1-5)-Likert Scale (Johns, 2010)
 8. Any other suggestions / observations (e. g. color, color code, orientation etc.)?
2. The icons which are passed both icon tests in usability testing are the ‘Well-Accepted’ icons.
 3. The icons which are failed in first test and passed in second test are ‘Well-Understood’ icons.
 4. The icons which did not pass both tests in usability testing are rejected or failed ones. These are ‘Difficult to Understand’ icons.
 5. Table 7 shows 2 out of 10 tourism icons that passed the first test and 5 tourism icons out of 10 icons that passed the second test.

RESULTS OF ICON EVALUATION USING SEMIOTIC ANALYSIS

Usability testing was the most important phase during this research work. A Table 7 shows a data about results of usability testing with tourism icons.

1. The each number indicates number of users who identified the corresponding icon in related tests namely, ‘Test without Context’ and ‘Test with Context’.

The observations and findings are explained with respect to three dimensions of semiotic analysis based on results of icon tests and user survey. The icons are divided into three category – ‘Well-Accepted’, ‘Well-Understood’ and ‘Difficult to understand’.

Semantic Dimension

Following are major observations based on semantic dimension of semiotic analysis of tourism icons under consideration:

Table 7. Results of usability testing with tourism icons

Sr. No.	Tourism Icon	State associated with Represented Icon	No. of Successful Users		Observations
			Test without Context	Test with Context	
1		Bihar	10	28	'Difficult to Understand'
2		Gujarat	64	69	'Well-Accepted'
3		Haryana	4	21	'Difficult to Understand'
4		Himachal Pradesh	22	72	'Well-Understood'
5		Sikkim	2	26	'Difficult to Understand'
6		Nagaland	6	23	'Difficult to Understand'
7		Kerala	24	35	'Difficult to Understand'
8		Rajasthan	17	55	'Well-Understood'
9		Jammu & Kashmir	42	61	'Well-Accepted'
10		Tamil Nadu	5	42	'Well-Understood'

1. The Tourism Icons: 'Gujarat' and 'Jammu & Kashmir' are the more popular icons which are identified by the maximum users correctly. 'Gujarat' icon has the 'Lion Face' which is the unique species found only in 'Gir Forest' in Gujarat and no-where-else in Asia. 'Jammu & Kashmir' icon has the 'Shikara' which is a type of wooden boat normally found in 'Dal Lake'. Out of 81 users, 64 had identified 'Gujarat' and 42 users
2. had identified 'Jammu & Kashmir' tourism icon in 'Test without Context'.
2. The Tourism Icon: 'Haryana' was not identified correctly because it shows only the bird 'Peacock'. Most of the users' opinion was that it represents 'National Bird of India', which is not the actual reason for its representation as depicted in Table 3. Only 4 out of 81 users identified this icon correctly.

Syntactic Dimension

Following are major observations based on syntactic dimension of semiotic analysis of e-Governance icons under consideration:

1. The tourism icon - 'Sikkim' was not identified correctly. The structure of this icon was not clear and understandable. Most of the users' opinion was that it is 'Rangoli' and one user even identified it as black magic. Only users which belong to user type - 'Central Government Employee' had given the correct answer.
2. The tourism icon - 'Nagaland' was not identified correctly because users did not identify this as a 'Ne Hut' which is crafted by Nagas – the residents of state of Nagaland.
3. The most of the users identified tourism icon - 'Rajasthan' as temple in 'Test without Context' as the structure in the icon looks like a temple. But when the Context of 'Rajasthan' was given, then the icon was properly identified as luxury tourist train by 55 users.
4. Few users suggested that the tourism icons - 'Nagaland' and 'Bihar' should have a better icon representation as these icons are very difficult to understand. Users have failed to understand the 'Ne Hut' which is crafted by Nagas from 'Nagaland' and 'Buddha Tree' which indicate the 'Bihar'. One user observed that the tourism icon - 'Kerala' was too abstract in the form of coconut tree and many of the users identified it as tourism icon for state of 'Goa'.

Pragmatic Dimension

Following are major observations based on pragmatic dimension of semiotic analysis of e-Governance icons under consideration:

1. Users felt that size of most icons was appropriate.

2. All users agreed that the all icons should be visible throughout the web pages visited for the improved understanding and comprehension.

FUTURE RESEARCH DIRECTIONS

Usability evaluation of icons is an interesting topic for usability researchers. The methodology proposed can be applied with selected icons from other domains with necessary alterations, if required.

CONCLUSION

During usability evaluation of tourism icons, it was observed that all of the selected icons have indexical features in them and therefore, they may not be easy to understand to users of e-Governance websites, who may be the users from Public or Citizens and also, from weaker socioeconomic or educational background.

It was also observed that the combination of different UEMs are effective in ensuring the overall communicability and usability of iconic user interfaces of e-Governance websites. These methods are as follows -

- Usability testing (comprehension by users).
- User survey (user preferences and feedback).
- Lexical analysis (concept by concept mapping of visual elements in the icon).
- Semiotic analysis (properties necessary for evolving a sign language out of icons).

These UEMs provide different insights pertaining to e-Governance icons and the icons are categorized as 'Well-Accepted', 'Well-Understood' and 'Difficult to Understand' icons.

ACKNOWLEDGMENT

We thank the project jury - Prof. M. V. Kulkarni. We also thank Mrs. P. A. Bailke and Mrs. Reshma Bhosale at VIT, Pune, India for their support to this research work.

KEY TERMS AND DEFINITIONS

E-Governance: Information and Communication Technology (ICT) that empowers the Government, its employees and citizens including women and weaker sections of society.

Lexical Analysis: The process of converting visual representations into a sequence of objects or tokens.

Semiotics: The study of signs and symbols.

Usability Testing: A technique used in user-centered design to evaluate a product or application by testing it with its intended users.

Virtual Tourism and Its Potential for Tourism Development in Sub-Saharan Africa

Paul Ankomah

North Carolina A&T State University, USA

Trent Larson

North Carolina A&T University, USA

INTRODUCTION

The rapid growth of ICT (Information and Communications Technology) has resulted in the development of innovative tools that could extend new opportunities for tourism destination marketers and potential tourists. The ICT-based tools provide the option of expanding the tourism product and tourism experience into the realm of Virtual Tourism (VT). VT has been defined as an ICT-based tool that can facilitate potential tourists' experiencing tourism attractions via the medium of Virtual Reality (VR) without visiting these tourist destinations. Since the tourism product is intangible and therefore cannot be pretested by the potential tourist before purchase, VT makes it possible to have a sense of the experience through immersion in VR. This chapter focuses on how the phenomenon of VT could be explored to realize its full potential, particularly by Sub-Saharan African countries. The chapter is divided into six sections. The first section reviews the literature on the concept of VR and also discusses VT in the context of VR. The section also examines the ICT components that support VR and consequently VT. The second section explains the reasons for the rise of VT and identifies some of the efforts and attempts (e.g. teleporter booths with 4D renditions of exotic destinations; virtual walks through historical sites) that have been made to develop VT as a part of the tourism industry.

The third section, examines some tourist attractions that could be marketed in the form of VT in Sub-Saharan Africa (SSA) to add value to the sub-region's existing physical tourist attractions. The section also identifies potential Sub-Saharan African VT markets. The fourth section identifies problems and provides suggestions to address problems that might scuttle these efforts at VT development. The fifth section recommends some areas for future research in VT and the sixth and final section provides some concluding remarks.

BACKGROUND

VT is an ICT-based tool that involves participant immersion and interaction (via visual graphics, sound, etc.) with the culture, history or other aspects of a tourist destination without physically traveling there (Ali & Frew, 2014). Sussman & Vanhegan (2000) indicated that VT is a convergence of human and computer interfaces to establish a 3D illusion of virtual (nonphysical) travel experiences. VT is also referred to as simply cybertourism (Prideaux, 2002). There are many technology-based activities assumed to belong to the realm of VT (e.g. panoramic photographs of a location). One of the fundamental characteristics of a VT experience is the level of interactivity by the person within the virtual environment. Creating a more realistic human experience within the

realm of VT requires a technological framework that allows the user to establish a presence in a virtual environment. This framework is known as VR.

VR is “a medium composed of interactive computer simulations that sense the participant’s position and actions and replace or augment the feedback to one or more senses, giving the feeling of being mentally immersed or present in the simulation (a virtual world)” (Sherman & Craig, 2003, p. 13). Pinho (as cited in Piovasan, Passerino & Pereira, 2012, p. 296) suggests that the essence of VR is captured by three fundamental purposes: immersion, interaction and involvement. Immersion refers to the degree to which the person is disengaged from the real world and perceives a connection to a virtual world synthesized by computer technology. The term interaction connotes the user’s ability to alter or reshape components of, or objects within a virtual environment. Involvement means that the user can navigate the virtual space (either actively or passively) to the degree desired.

In order for a VR application to meet its purposes and function properly, a VR system must be in place. A VR system consists of hardware—a computer/VR engine connected with input and output devices, e.g. keyboard, mouse, a helmet or head mounted display (HMD); software (application software and databases saturated with useful information) (Sherman & Craig, 2003). The market value of VR technology is projected to increase from \$980.4 million in 2014 to approximately \$1.66 billion by the year 2020 (MarketsandMarkets, 2015). According to IHS Technology, the demand for VR products will increase and approximately 7 million VR headsets will be purchased by consumers by the end of 2016 (Graham, 2016).

VR systems are classified by their technological sophistication, level of immersion in the virtual world and come in four varieties: 1) non-immersive systems include simple electronic 3D simulations viewed through a portal and displayed by a com-

puter monitor and manipulated by standard input devices (e.g. mouse, keyboard). 2) semi-immersive systems (or augmented reality systems) combine digital images of virtual environments displayed in devices (e.g. HMDs) together with objects from the real world. 3) projected systems—involves the creation of a physical space outfitted with display screens, video projectors and one or more users wearing input devices such as stereo glasses or haptic gloves. The computer-generated graphics displayed on the screens update or refresh in response to the user’s body movements as captured by the tracking devices imbedded in the glasses or gloves. An example of this would be Cave Automatic Virtual Environment (CAVE), a specific kind of multiple projection room that allows one or more users to experience virtual worlds without being fully immersed. 4) complete immersion systems rely on HMDs, tracking devices and haptic gloves to send feedback to the display system (Blackledge, Barrett, & Coyle, 2011). Some of the other terms used in place of VR include: virtual environment, artificial reality, virtual worlds, and artificial worlds (Bamodu & Ye, 2013).

Another closely related term vital to understanding VR is telepresence. Telepresence is the extent to which an individual feels present in a computer-generated, multi-sensory environment and possesses the capacity to remotely interact with or manipulate the form/content of the environment in some way (Steuer, 1993). Telepresence makes possible the use of remotely-operated devices such as robots, vehicles and drones that perform jobs in high-risk areas such as nuclear plants, law enforcement, military operations, and space exploration, etc. (Sofge, 2015). The telepresence concept has many applications including utility for VT.

Within the tourism industry, VR systems apply in several general areas such as planning and management, marketing, entertainment, education, accessibility and heritage preservation (Gutentag, 2010). The next section examines some of the reasons for the spread of VT.

VIRTUAL TOURISM

Reasons for Expansion and Development of VT Products

There are several possible reasons for the expansion of VT in the travel industry. With the rise of terrorism and groups such as ISIS operating in many countries, people are fearful of leaving the safety of their own country. VT provides opportunities to participate in tourism activities without being physically present in the location. Additionally, VT has the advantage of allowing individuals to experience the destination and make evaluation prior to the actual purchase and subsequent travel to the destination.

Another reason for VT offerings could be the cost of travel. With travel related expenses soaring, the overall cost of traveling extensive distances may be prohibitive. Also, VT could appeal to those afraid to travel or physically unable or unwilling to sit for 10-15 hours in an airplane to experience a distant location with all the associated discomfort and inconvenience of security check points, delayed or cancelled flights.

Additionally, the rapid development of technology has the potential to make VT more easily accessible to people who already have access to ICT. With the trend towards more home-based leisure (e.g. computer games, online entertainment) on the rise, VT activities are likely to become ubiquitous like videogames (Williams & Shaw, 2009). VT connects people with a gamut of tourism destinations without the need for money or resources or having to go to those places (Cheong, 1995). Through virtual channels, people can experience a variety of places and even jump from one continent to another in minutes or go back in time to see digital replicas of ancient civilizations or navigate newly-created fantasy worlds (Cheong, 1995).

VT could also be a way to travel when time is in short supply. There is also the convenience factor. Virtual tourists don't have to know a language or have to go through the trouble of finding

a location in an unfamiliar destination. They also don't need to worry about monetary exchange, food, weather, etc. VT is predictable and appeals to people who don't like surprises.

Visits to remote areas via virtual technology always occur under optimal conditions, i.e. with sufficient lightening, no crowds and without limits on the length of stay (Kaminsky, Arnold, & Benson, 2014). Furthermore, VT could serve as recollection for people who have been to a destination and want to reminisce over the experience and to see what changes have occurred if any, since their last visit (Hyun, Lee, & Hu, 2009).

Tourism providers have sought to utilize the VR framework to create useful applications for potential tourists to have easy access to destinations and these applications are pervading the travel industry. The remainder of the section examines how tourism providers are manipulating non-immersive, semi-immersive, and complete immersive systems of VR to complement existing tourism offerings and develop new VT products.

Non-immersive system applications for VT have been available for quite some time and appear in 2D and 3D formats. Such computer-generated renderings of historical sites allow visitors to engage with ancient buildings, other artifacts and virtual people (from that time period) in a digital world (Catalano, et al., 2011). YouVisit.com is an example of a company that specializes in the development of a variety of virtual 3D tours including parks, hotels, and cities in various parts of the world. Tourism websites that feature 3D renderings of natural and cultural elements of a destination to capture the essence of the place are more likely to result in more enjoyable visitor experiences (Huang, Backman, Backman, & Chang, 2016). Providing online VR simulations of resorts/facilities before travel begins is becoming a necessity for tourist destinations to maintain their relevance in the competitive global tourism market (Clayton, Ajagunna, & Pinnock, 2014).

Semi-immersive systems (also referred to as augmented reality) are those that combine virtual with real world elements of the tourism industry.

For example, the Marriott Corporation, as part of its *Travel Brilliantly* campaign, has developed teleporter booths that use VR to simulate a beach experience in Hawaii (Shu, 2014). Each booth features virtual video content displayed via HMDs and headphones that must be carefully synchronized with 4D content: the action of ocean waves simulated by misters, the warmth of breezes created by heat blowers and the sensation of tactile simulators on the booth floor to create the feeling of walking in sand (Shu, 2014).

HMDs and projection systems such as CAVEs are two commonly used applications of VR to attract tourists to theme parks in North America (Jelinski, 2013). At Disney Quest, HMDs are used in Aladdin's Magic Carpet Ride while CAVEs are part of Pirates of the Caribbean: Battle for Buccaneer Gold and Hercules in the Underworld attractions. The world's first exclusively VR theme park is slated to open in Utah in 2016; it will feature physical objects from the real world and simulated 4D effects of artificial wind, mists of water, and heat lamps (Metz, 2015).

Landmark Entertainment, a company that develops rides and other attractions at Universal Studios Hollywood, Paramount Parks and some Las Vegas hotels, is initiating a new VR project that includes the construction of L.I.V.E. Centers at shopping malls in China that would provide patrons opportunities to experience virtual animal parks, aquariums and museums through the use of HMDs and eventually, using the same technology, virtual theme parks accessible online from any location in the world (Roettgers, 2015). Besides semi-immersive systems there are complete immersive systems that do not rely on real objects from the physical world.

Complete immersive systems are creating VT offerings and these are helping to stimulate visits to tourism destinations in various parts of the world. In conjunction with the VisitScotland expo, a company called Augmented Visualisations has developed a 3D application that takes visitors on a virtual tour of local landmarks such as Arbroath

Abbey, Angus Glens and Glamis Castle to encourage them to visit the country (British Broadcasting Corporation, 2015). Another company in Scotland has undertaken to develop a realistic VR model of a ship (RSS Discovery) used by Captain Robert Scott to sail to Antarctica (British Broadcasting Corporation, 2014). Once the digital scanning of the original ship is complete, visitors will be able to virtually visit the bridge, climb the rigging and explore areas below the deck of the ship from the comfort of their own living room (British Broadcasting Corporation, 2014). Quantas has partnered with Samsung Electronics to develop an inflight entertainment service that relies on VR headsets to show tourists virtual images of attractions, destination accoutrements and other products offered by the airline (Quantas, 2015). Marriott has implemented another program to promote the use of HMDs by guests. This program is called *VRoom Service* and permits hotel patrons to check out VR headsets to view of virtual postcards containing highlights from trips to destinations in Rwanda, Chile and China (Graham, 2016).

VT is still in its infancy, however, tourism-related businesses in collaboration with ICT companies have created VT experiences on an experimental scale in their tourism promotion activities. For instance, Thomas Cook has teamed with Samsung and Visualise (VR film makers) to create a series of VT clips labeled 'Try Before you Fly' of retail shopping experience of the U.K., Germany and Belgium. Potential visitors to these countries can virtually visit their favorite retail stores prior to their actual visitation (Graham, 2016). Another example of VT on an experimental scale is provided by Matoke Tours which recently released a VT brochure featuring unique tour offerings (gorillas, safari balloon flights, safari boat rides, a gamedrive in Queen Elizabeth National Park) of Uganda (Graham, 2016). The purpose of virtual brochure application was to "convey the intensity and emotion of the travel experience before the journey has even started" (Graham, 2016).

Another example of a pre-trip immersive virtual tourist experience is found in British Columbia. Destination BC, marketed by the Crown corporation, offers a virtual boat ride along British Columbia's coast or a virtual hike through the Great Bear Rainforest (Meissner, 2015). The digital 3D video becomes animated through Oculus Rift headsets and headphones. Capturing the spectacular views for these unique tourism offerings required special cameras and the use of drone technology (Meissner, 2015). Landmark Entertainment is also currently exploring options for the creation of virtual theme parks accessible online through HMDs from any online location in the world on a daily basis (Roettgers, 2015). Each of the aforementioned VR systems can create unique VT products that complement actual trips to locations throughout the world.

All tourist attractions could be experienced through the medium of VT. Consequently, it is reasonable to assume that similarly all tourist attractions in the sub-region that people physically travel to visit could also be experienced through VT. The Sub-Saharan African VT offerings could be transmitted in all formats previously discussed. SSA has many categories of tourism products that could appeal to tourists from international markets as VT offerings. Some of these products could include safari tourism (viewing Africa's *Big Five* via various modes of transportation or on foot), natural products (birdwatching, tracking gorillas, sightseeing, hiking, etc.), resort tourism (beach tourism, lake tourism, watersports, etc.) (World Bank, 2009); heritage tourism (Yankholmes & McKercher, 2014); volunteer tourism (Tomazos, 2010); medical tourism (Connell, 2011; Ramirez de Arellano, 2011); and education tourism (Ankomah & Larson, 2000). Developing VT products from the tourism resources of SSA could complement existing tourism development efforts and could also generate new tourism experiences. The next section identifies the potential market for VT in SSA.

Possible Sub-Saharan Africa VT Markets

H

This part of the section describes the VT markets in SSA and then identifies some possible areas for development in the sub-region. According to the 2009 World Bank Report, the top five international markets for SSA are France, UK, US, Germany, and Portugal; identified emerging markets for the sub-region include Spain, Australia, India, China, and Russia (World Bank, 2009). The availability of VT options could possibly substantially increase the numbers of potential tourists from these areas who might want to either physically visit or remotely-experience the sub-region. These countries are also among the leading innovators and adopters of ICT.

Potential Problems Associated with Implementation of VT Strategies by Sub-Saharan Africa Countries

Potential problems that could derail or impede strategies for developing and implementing VT products in the sub-region may include the following:

1. **Weak Technological Infrastructure:** Many countries in SSA have a marginal technological infrastructure at best. Though cell phones have become commonplace in the sub-region, there remain many antiquated ICT systems in operation. For instance, many locations continue to rely upon dial-up modems to transmit data back and forth. Connecting sophisticated VR systems to outdated hardware could result in VT applications that do not function at all or that operate inefficiently. These kinds of difficulties could frustrate technological-savvy tourists wanting to engage in VT portrayals of tourist destinations in the sub-region.

2. **Erratic Supply of Electricity:** Electricity is not a reliably-available commodity in the sub-region and extended disruptions in service are common. This could present a problem for keeping essential computer hardware online and also lead to damage of other equipment needed for the development and maintenance of VT offerings. It makes no difference how modern the ICT equipment is if there is no consistent source of electricity, VT products will not be available.
3. **Lack of Foreign Exchange:** Due to a lack of foreign exchange, many Sub-Saharan African countries do not have the financial resources necessary to update obsolete computer equipment and to purchase new technology needed to enable VT activities.
4. **Constantly Evolving Technology:** Technological innovations come out so rapidly that countries in SSA already behind the adoption curve may never find sufficient resources to purchase upgrades and other equipment necessary to remain competitive with the developed world in terms of VT applications.
5. **Technology Skills Deficit:** Another problem facing countries in the sub-region is the lack of ICT skills in the areas of system analysts, programmers, maintenance experts and consultants (Edoho, 2013). With an insufficient number of people with expertise in computers and other technological skills, many VT projects could remain on hold indefinitely or only become available on a limited basis. Also, there may be tourism stakeholders that are reticent to adopt additional technologies because they are not educated about or familiar with how the new technologies operate.
6. **Underdeveloped Domestic Tourism Market:** For any strategy to implement VT to be sustainable over the long-haul there must be some buy-in by the locals in countries of the sub-region and this may be difficult to accomplish. Many local tourism

stakeholders may be reluctant to adopt the VT approach because they may feel that it is only a passing fad and a waste of scarce resources. Any successful attempt to make VT applications a significant part of tourism must also include development of the domestic tourism market, particularly inter and intra-regional products.

The next section identifies some solutions to these problems and also offers some recommendations that could increase the chances of making VT development efforts successful.

SOLUTIONS AND RECOMMENDATIONS

The previous section identified some of the major problems associated with the development of VT products in SSA. This section provides some solutions to these problems including:

1. **Strengthening Technological Infrastructure:** The technological infrastructure of the sub-region could be strengthened by these countries pooling their resources to purchase the necessary computer hardware and other devices that make VT feasible.
2. **Improving Supply of Electricity:** The problem of erratic supply of electricity could be addressed by pooling resources of African countries to purchase better grid network equipment to improve the efficiency of the delivery of electrical power to its citizens. Countries could also collaborate to develop solar power that could compensate for the shortage of electricity generated through other sources.
3. **Enhancing Foreign Exchange:** Sub-Saharan African countries could make up for the lack of foreign exchange by pooling their resources to buy much-needed ICT components. The countries could also find

areas where they can eliminate waste of scarce resources. One way to do that would be to eliminate political corruption and cronyism in government.

4. **Keeping Pace with Evolving Technology:** The only way for countries of the sub-region to meet the problem of rapidly changing technology is to pool resources to be able to afford the onslaught of technological innovations. These countries could also engage in research on emerging technologies to determine which ones will be the best long-term investments.
5. **Closing the Gap on Technology Skills Deficit:** The problem of the technology skills deficit could be addressed by dialoging with the diaspora from Sub-Saharan African countries and invite them to return to become a nucleus (similar to what China and India have done) to help train locals in how to use and maintain the computer components and other devices that comprise VT. Also, for those diasporas who wish to remain in their host countries, a virtual community could be established to transfer technology skills while on sabbatical or through distance education.
6. **Developing Domestic Tourism Market:** Sub-Saharan African countries could make the VT effort more sustainable in the long-term by continuing to promote and develop the domestic tourism market in the sub-region. This could be done by encouraging locals to participate in the creation and marketing of VT experiences. In so doing, they could create new forms of tourism through drone technology and this may help stimulate greater demand for domestic tourism and VT products.

In addition to solutions to the problems associated with developing VT products, this section also provides some recommendations that could make these virtual offerings more attractive and feasible. It is suggested that Sub-Saharan African

countries organize and house their VT products in one location on the internet. This could be the website of the country's NTO (National Tourism Organization) at the country level or other multinational organizations. Tourists looking for a VR experience could easily find and engage with VT resources.

FUTURE RESEARCH DIRECTIONS

There are several avenues that future research could take to advance the spread of VT products in SSA. Some these include:

1. **Determining VT Readiness:** Studies could be conducted to determine the degree of readiness of tourism stakeholders for accepting VT as a viable and additional option to traditional tourism offerings.
2. **Effectiveness of VT Products:** Research studies could be designed to discover whether the use of VT products prior to travel played a role in decisions to travel to SSA.
3. **Appropriate Areas for VT Development:** Researchers could sample the opinions of tourism stakeholder as to which kind of tourism attractions in the sub-region are best-suited for VT applications.
4. **Impact of VR on the Future of VT:** Research studies should focus on identifying the future direction of VR and its potential to impact VT.

CONCLUSION

Countries of SSA are looking for new ways to generate revenue to support their meager resources. Tourism is one of the areas that countries have been focusing on in their efforts to expand economic development resources, especially foreign currency. VT has the potential to increase total tourism revenue in the sub-region. VT also presents the potential to generate additional resources

by giving these countries the opportunity to offer different prices to potential tourists by charging different rates for non-immersive, semi-immersive or complete immersive experiences. The countries in the sub-region have an opportunity to display tourism artifacts (e.g. carvings, traditional clothing, trinkets, etc.) on the websites that might be of interest to non-visitors who may still want to own these artifacts as souvenirs. Additionally, lesser-known tourism destinations have the opportunity to gain global exposure for their tourism attractions via VT. Furthermore, by making efforts to be involved in the VT industry, these countries will ensure that they are not left behind when VT becomes the phenomenon of the future.

KEY TERMS AND DEFINITIONS

Head Mounted Display (HMD): A digital display device worn over the head that makes viewing of 3D computer images possible and leads the user to semi-immersion or total immersion in a virtual environment.

ICT: Electronic devices (e.g., computers, cell phones) and the wired or wireless infrastructure necessary for communication and other unique services such as e-learning, social networking and videoconferencing.

Immersion: The level at which someone engaged in a virtual environment senses the real world outside of it.

Interactivity: The degree to which a user of a VR system is able to control the content and appearance of a simulated environment.

Virtual Community: A cooperative group of individuals from various geographical regions that come together via ICT to solve social, business or educational objectives.

Virtual Reality: Computer-generated simulations of real-world objects and locations (and sometimes imaginary ones) that provide stimulation to the senses of the user and lead to a sensation of being present in a replicated environment almost as if it were the original.

Virtual Tourism: An ICT-based tool that uses digital images and sensory feedback to simulate tourist attractions available at remote destinations.

INTRODUCTION

Affective computing is the broad domain encompassing all of the hardware, software and underlying theoretical models underpinning the development of affect sensitive computer systems. Such systems facilitate more intuitive, natural computer interfaces by enabling the communication of the user's emotional state. Despite rapid growth in recent years, affective computing is still an under-explored field, which holds promise to be a valuable direction for future software development. Human-computer interaction has traditionally been dominated by the information processing metaphor and as a result, interaction between the computer and the user is generally unidirectional and asymmetric. The next generation of computer interfaces aim to address this gap in communication and create interaction environments that support the motivational and affective goals of the user.

This chapter will introduce and elaborate on the field of affective computing. First the background and origins of the field will be discussed. Next the elements of affective computing and affective human-computer interaction will be discussed along with associated concerns and issues. Next, examples of the diverse range of affective computing applications in current and recent development will be provided. Finally, the chapter will present a discussion of future directions for this promising technology, followed by some concluding remarks.

BACKGROUND

Computer usage has traditionally been regarded as a rational activity in which emotions are not involved. This view, however, has been changing as the importance of emotions in all aspects of human thinking, activity and interaction is becoming more apparent. Human interactions do not just include those with other people, but also with their surroundings, including inanimate objects. One such object that has a big role in the day to day life of many people is the computer.

It is not uncommon for a person to spend more hours in a day interacting with a computer than face to face with other people. For this reason it is important to design computers that are user-friendly and easy to use (Preece et al., 1994). One important aspect of this drive towards user-friendliness is that the user should be able to use his or her natural way of interacting rather than having to learn new ways of working (Norman, 1988). The goal of improving the interaction between users and computers requires that emotions be taken into account in this interaction.

The field of HCI has greatly matured over the last several decades since the first conference on human factors in computing systems was held in the early 1980's. Since this time the emphasis within HCI has shifted from a focus on trained systems operators, to analyzing how technology influences the general user. To this end, there has been a substantial amount of attention devoted to

the concept of usability, as well as the role of the user in the development of successful interfaces. Usability is simply defined as “the extent to which a product can be used by specified users to achieve specific goals with effectiveness, efficiency, and satisfaction in a specified context of use” (International Organization for Standardization, 2010). This broad definition sets the stage for the fact that usability is a complex construct that can be influenced by a large number of external factors including context or environment.

In the early 80s, the role of a HCI specialist would be to evaluate interface components such as menus or terminology. As the field progressed, and the specialists came to realize the broader applicability of their work, new directions and specializations were created. The term “user-centered” is extensively used in the field of HCI (Karat & Karat, 2003) when describing approaches to building usable systems. For user-centered design, the main focus is that the needs of the user are used as a way to inform design (Vredenburg, Isensee, & Righi, 2001). This perspective is also sometimes referred to as human-centered design, or human centered computing (HCC). HCC broadly describes the methodology that would be applied to any field that uses computers in any form where users directly interact with them (Jaimes, Sebe, & Gatica-Perez, 2006). Thus HCC aims to integrate human sciences (such as cognitive and affective) into the existing body of computer science and HCI knowledge with a human focus throughout the lifecycle. HCC is said to incorporate social and cognitive sciences more closely than traditional HCI (Foley, 2006).

The recognition that interaction is not limited to simple interface modalities gives support to the development of new technologies. The ISO 9241 standard encapsulates this view in the following high level goal for user-centered design: “the design addresses the whole user experience” (International Organization for Standardization, 2010). This acknowledges that the HCC principles of cognitive and affective design are important

when developing usable software and systems. To this end, a successful user interface would have an understanding of what emotions are, how they can be identified and what the implications of various emotional patterns are for a given interaction situation.

The term “affective computing” was coined as long ago as 1997 by Rosalind Picard, who defined it as “computing that relates to, arises from, or deliberately influences emotions” (Picard, 1997a, p. x). This is the most comprehensive and widely used definition and is often cited. Picard, a pioneer in this field, reports that the initial response to the very concept of emotion-sensitive machines was somewhat lackluster (Picard, 2010), and it is interesting to observe the dramatic rise in interest from both developers and the research community in recent years.

Affective computer interfaces improve human-computer interaction by enabling the communication of the user’s emotional state. The growing interest in affective computing arises from findings in psychology and physiology which demonstrate the importance of emotional state in human behaviour (Partala & Surakka, 2004).

Emotion and cognition are linked and there is evidence of emotion influencing aspects of cognitive performance and decision making (Cytowic 1989; Eysenck et al. 2007). The interaction between affect and cognition is bi-directional, thus the underlying affective state of the individual will also influence the outcome of various cognitive processes. This, predictably, has far ranging implications. There is evidence that emotion has an impact on the speed at which information is processed (Öhman, 2001) and whether it is attended to (Anderson, 2001; Vuilleumier, 2001). Emotion also has a relation to motivation in that evaluations or feelings regarding the current situation will largely determine the action that is taken in response. Therefore, emotions are often precursors of motivations (Oatley, 1992). Memory is also impacted by emotional state, and again there are many mechanisms by which this

can occur (Reisberg & Hertel, 2003). Thus there are substantial potential benefits to be had from the development of user interfaces that support users' emotional, as well as cognitive processes, in their day to day work or life.

Currently, affective computing research is conducted in a large number of areas including education, autonomous agents, games and healthcare. There is also a rapidly growing body of published literature on the subject with 2010 marking the launch of the *IEEE Transactions on Affective Computing*. This is the first cross-disciplinary, international journal dedicated toward disseminating the results of research in areas such as theories of affective human-computer interaction systems, algorithms to detect and respond to emotions, and applications of affective computing.

AFFECTIVE HUMAN-COMPUTER INTERACTION

Although a computer will not actually experience emotions in the same way that a human would, the quality of interaction has been shown to improve even if the system *appears* to do so. Klein, Moon and Picard (2002) conducted a study in which users interacted with a computer system that was designed to deliberately elicit negative feelings of frustration. It did this by inserting random delays or periods of unresponsiveness to hinder the users from carrying out the goals of the study. The results demonstrated that if the computer system provided users with the ability to vent their frustrations (as a form of affect-support), users continued to interact with the frustrating system significantly longer than if no affect-support was provided. Empathic agents have also been successfully used in software to improve usability. Prendinger, Mayer, Mori and Ishizuka (2003) utilized an on-screen animated agent to provide empathic support to users who had been carrying out a frustrating computer interface task. Findings indicated that a character demonstrating empathy

may decrease users' levels of experienced stress. For these findings to be applicable for real-world affective interfaces, a key aspect of software functionality is the ability to detect the emotional state of the user.

Detection of Affective State

Mehrabian (1981) is often cited for his 7%-38%-55% rule of non-verbal communication which simply states that in human communication, 7% of the message is communicated by the words, 38% by tone of voice and the remaining 55% by body language. This is particularly relevant when we consider the expression of emotional content, or affect, which is largely non-verbal in nature. The use of subtle non-verbal communication methods is not only desirable but almost a necessity for a successful affect detection system to operate. Methods for inferring affective state are numerous but may be broadly categorized into a few areas, which are described below.

Self-Report Measures

A number of self-report measures of affect have been developed and used in research on mood and emotion; many of these share similar features but also have differences in the way that the responses are formatted and the way in which tests are conducted. Many of the most prominent self-report affective measures involve presenting lists of adjectives to the subjects, and obtaining a rating as to how appropriate or strong these particular emotions are (e.g. POMS (McNair, 1971) or PANAS (Watson, Clark, & Tellegan, 1988)). Self-report measures are a valuable instrument in the development and assessment of affective computer interfaces. However, as their use often requires the user to be interrupted or to recall a memory of an event, these have limited applicability for end-user applications which generally aim to produce the most natural interaction environment possible.

Observable Traits

The use of observations to infer the emotional state of an individual stems largely from the work of Ekman and Friesen (1978) who theorized a relationship between particular facial configurations and the underlying “basic” emotions present and later derived lists of facial expressions that would be used as markers for particular emotions. More recent work has called for other “non-basic” emotions to be considered within affect sensing systems, as different application domains may bring different emotional states into relevance (D’Mello & Calvo, 2013). Similar techniques may be applied to the observation of other features, such as the user’s posture or gestures. Observable traits have the benefit that an affective application may utilize this source of information with little or no user intervention. Subtle changes in facial expressions and posture occur without conscious effort on the part of the individual and may also reveal a deeper insight into the underlying affective state. One disadvantage of these methods is that the technical and implementation environment is often quite “noisy” and the success rate of automatically detecting affective state from natural expressions or gestures may be impaired.

Psychophysiology

Researchers have become increasingly aware that a critical component of emotion is physiological activity. According to some theories, if there is no physiological reaction there is no emotion (e.g. Schachter & Singer, 1962). It is theorized that every psychological event or affective state has some physiological referent (Cacioppo & Tassinary, 1990), therefore the issue is not so much of whether or not a physiological signal is present, but rather which aspects of emotion may be inferred from this signal. There are many advantages to this approach. Physiological signals are unconscious and do not carry any of the subjectivity of self-report measures, furthermore they bring about the potential for real time measurement with no need

to interrupt or otherwise distract the user. Finally, as technology advances, physiological sensors may be suitable for incorporating into existing physical interfaces to ensure a more natural interface which the user need not be constantly aware of. Recent developments have permitted the integration of physiological sensing into wearable form factors (e.g. Lanatà, Valenza, & Scilingo, 2012) and even enabled physiological sensing from existing commodity devices such as smartphones (Hernandez, McDuff, & Picard, 2015).

APPLICATIONS OF AFFECTIVE COMPUTING

Affective computing applications have potential uses in practically any situation where a human-computer interaction is taking place. Technology that can recognize and even express affect can provide insights into human-computer (and in some cases human-human) interactions. Measuring the stress or difficulty caused by a system may also allow developers to pinpoint problems, or simply allow the system to be improved by being able to respond in a more natural and realistic way. Such technologies have been successfully implemented in very diverse environments. These include robotic personas (Breazeal, 2003), learning companions (D’Mello, Lehman, & Graesser, 2011; Sarrafzadeh, Alexander, Dadgostar, Fan, & Bigdeli, 2008), games (Gilleade, Dix, & Allanson, 2005) or wearable computers (Picard, 1997b)..

Sociable humanoid robots present a novel and under explored area of human-machine interaction. Traditionally robots have been utilized for functional roles such as automation or inspections, in roles that require autonomy and minimization of human interaction. However, as robots may be used for any number of applications, including domestic use, the requirement for natural and usable human-machine (in this case robot) interaction, presents itself.

Humanoid robots may express affective states in a number of ways. Robotic characters, if human

like in appearance, are well suited to affective expression as they can communicate in ways which emulate the natural communication modalities of humans. This can include non-verbal communication such as gestures, facial expression or body positioning. One example is Kismet: a socially expressive anthropomorphic robot. Kismet perceives a variety of cues from visual and auditory channels and delivers affective information back to the human through gaze direction, facial expression, body posture, and vocalization (Breazeal, 2002). The robot possesses a computation model of emotion, in which affective state is sensed, used as part of the internal decision (action) making strategy, and communicated to the human.

As mentioned, animated agents may also be used in a similar way to communicate affective content and to put the user in a positive and constructive affective state to maximize enjoyment, entertainment, learning or productivity. Education is an area in which affective computing applications have shown promise, partly due to the increasing reliance on online and computer mediated learning and teaching strategies. Goleman (1995) reported that expert teachers are able to recognize emotional states of students, and respond appropriately to positively impact learning. Whilst the way in which this is accomplished is not well documented a key element involves the recognition of negative affect or states that are detrimental to learning and guiding the learner into a more positive and constructive state. Intelligent tutoring systems incorporating an emotional or affective model are known as affective tutoring systems. An affective tutoring system is thus any tutoring system that can adapt to perceived emotion. This may be to respond to any negative emotions being experienced by the learner, or to interact in a manner that is more natural and engaging for the learner.

A number of such affective tutoring systems exist, that respond to different types of input. For example, AutoTutor is an intelligent tutoring system that interacts with learners using natural language and helps them to construct explanations

in simulation environments (Graesser, McDaniel, & Jackson, 2007). It detects the learner's affective state using physiological and facial expression analysis and conversational cues. Easy with Eve (Alexander, Sarrafzadeh, & Hill, 2006; Sarrafzadeh, et al., 2008) is an affect sensitive mathematics tutor. Affect recognition is performed by video analysis to capture facial expression and gesture information from the user. These systems have also been shown to be effective and result in increased learning, however are still not as effective as a one-to-one human tutor.

A number of affective games have been developed to encourage the user to express their affective states and to dynamically respond and adapt to this form of input. For example, in SenToy, the user interacts with a doll to communicate one of six emotions through gestures (Paiva, 2003). Other games utilize biofeedback to guide the user into certain affective states, for example in the game "The Wild Divine" (2012) the player needs to achieve a state of relaxation to interact and progress within the game environment. Affective interaction and expression has been identified as a valuable direction of research to develop more engaging and realistic games (Hudlicka, 2009).

Wearable computers provide a rich and diverse ground for evaluating and implementing affective technologies. The close contact with the user enables easy communication of subtle non-verbal cues that may be valuable indicators of affective state. In some cases, the affect detection capabilities may even be used to improve the users' own abilities to perceive emotions in others, and thus improve human-human communication. For example "expression glasses", developed at MIT provide the wearer with feedback about the emotional expressions of others (Scheirer, Fernandez, & Picard, 1999). This technology may improve the quality of life for those with autism or other disorders that impair human-human communication (el Kaliouby, Picard, & Baron-Cohen, 2006). Existing devices that are in close contact with the user may also have potential to be used as affect sensing devices, for example a mouse may sense

the user's stress levels (Kirsch, 1997), or a car steering wheel may sense when the user is falling asleep or identify lapses in attention (Gusikhin, Filev, & Rychtycky, 2008).

ISSUES

The diverse nature of affective computing applications described in the previous section highlights that this technology is successful and adaptable to a wide range of situations with positive outcomes. However, as many of the implementations are disparate and “one-off” in nature, it is potentially difficult to transfer findings from one particular domain to a new application. Furthermore, as this is a new and emerging field, there is little evidence of “shared best practice” aside from the high level principles that have been established regarding inference of affective state.

Affective computing applications are often built in the same way as more traditional applications, with the affective functionality inserted into the program architecture wherever the developer considers it appropriate. Consequently, the current trend for ad-hoc development in affective computing is hampering progress. Allanson and Fairclough (2004) noted that research in the area was disparate and uneven, and it seems that little progress has been made since then. One goal that has been identified in the literature is that of “device-independence” – any successful solution to the issue must be capable of abstracting over multiple implementation environments which may have different outputs, manufacturers and operating requirements.

Due to the diverse nature of implementation, and the many methods by which affective information may be gathered, affective computer interface components often need to deal with many different types of data (all with different characteristics and requirements for processing). This often presents a complex signal processing task, which involves a number of stages from extraction of the raw signal to analysis and transformation of the data into a

computer input with well understood parameters. For this reason it may be necessary to add a layer of signal processing between the intelligent sensors and the interface to limit the complexity of the interaction techniques (Allanson, 2000).

It becomes apparent that the one commonality amongst affective computing applications is the extent to which developments are unique and tied to a particular implementation. Hamming (1969) stated that “a central problem in all of computer science is how we are able to get to the situation where we build on top of the work of others rather than redoing much of it in a trivially different way” (p.10) – an observation that is valid to this day. As affective applications are highly specialized and complex, there has to date been no discussion regarding the concept of reusing existing affective applications in new problem domains and situations. Furthermore, the potential for adding affect support as an additional layer above existing software has not been investigated thoroughly to date. Aist, Kort, Reilly, Mostow and Picard (2002) demonstrated the utility of adding emotional support to an existing tutoring system, and noted that this approach may be useful for future developments. Certainly, the ability to augment existing software with affect sensing capabilities could for the most part turn the entire operating system and all its application software and tools into an affective computing application. This would be a breakthrough for those who envision affective computing as being a part of the entire computing experience rather than the domain of a few isolated applications

FUTURE TRENDS

In a relatively new field such as affective computing, theories regarding emotion, tools, methods and software are constantly evolving and improving as our knowledge grows. The rapidly developing body of research in the field of affective computing gives a clear indication that affective computing is going to play a major role in the future of human-computer interaction.

The domain of affect sensing technologies is one which will directly be improved as advances in computer technology take place. The increased processing power and portability of modern computing devices makes advanced signal processing and affective pattern recognition, more feasible. Furthermore, as computers become ubiquitous and become integrated into vehicles, clothing and our surroundings, the opportunity for greater physical contact between user and machine increases and makes new input paradigms increasingly viable.

Education is an area in which applications of affective computing are highly applicable and substantial research has been carried out in this area. The fact that interaction with computers is a fundamental part of study in most disciplines renders this a prime candidate for affective computing developments. Endowing a computer with the ability to respond to affective state should enhance learning outcomes and have a positive impact on the user experience of e-learning. Furthermore with the increased dependence on online learning, such technology may be in even more demand as teachers no longer have access to students' non-verbal cues in classrooms (Crosby, Brent, Aschwanden, & Ikehara, 2001). Interest in the educational implications of affective computing is not limited to the academic research community. In 2012, industry analysts Gartner Research discussed how the field is on the rise in education. Whilst most of the affective tutoring systems are in the proof of concept stage, the advice given to education institutions is to track the progress and developments in the field and that those with a large online presence should immediately get involved. Affective computing is described as having "the potential to bring back a bit of the lost pedagogical aspect of in-classroom learning and increase the personalization of online learning" (Lowendahl, 2012, p. 15).

CONCLUSION

Affective computing facilitates more intuitive, natural computer interfaces by taking into account the emotional state of the user. As such, affective computing holds great promise for improving human-computer interaction. This chapter has provided an insight into the field of affective computing: covering the origins of the field, the underlying elements of affective computing, and highlighting issues in the field. Detailed examples of a diverse range of affective computing applications are provided and future directions have been identified.

KEY TERMS AND DEFINITIONS

Affective Computing: Defined by Picard (1997a) as “computing that relates to, arises from, or deliberately influences emotions”.

Affective Human-Computer Interaction: Affective HCI incorporates the communication of affective state information as an interface modality. This aims to enrich the quality of interaction and permit the user to employ more intuitive methods of communication.

Affective State: This term refers to the experience of feeling the underlying emotional state. The description often distinguishes between the more diffused longer term experiences (termed moods) and the more focused short term experiences (termed emotions).

Human-Computer Interaction (HCI): The study of how users interact with computer based devices. This includes techniques for assessing elements of the effectiveness or ease of use of an interface as well the development of more intuitive and natural interfaces.

Psychophysiology: Research suggests that all underlying affective states have some physiological manifestation that may be subtle, but potentially observable. The field of psychophysiology bridges the domains of psychology and physiology with the study of how these aspects of human experience interact.

User-Centered Design: A type of user interface and interaction design in which the main focus is that the needs of the user are used as a way to

inform design. This often involves a participatory or cooperative design approach in which designers and users work collaboratively.

Wearable Computers: Any portable, miniature devices that are computer based and worn by

the user as part of their clothing or accessories. Increasing miniaturization and widespread use of portable computers (including smartphones) makes this a viable and promising domain in which affective computer interfaces may be developed.

H

Computer-Assisted Indian Matrimonial Services

Robert Leslie Fisher

Independent Researcher, USA

INTRODUCTION

People seeking romantic relationships have advertised for partners on the internet in both developed countries (e.g. U.S.A.) and developing countries such as India since that first became possible twenty or more years ago. However, advertising patterns differ among societies with more advertisements in the United States by people looking for short term relationships (as evidenced by the success of such sites as Tinder)), and more advertisements in India from people looking for suitable spouses in a society where overwhelmingly people have arranged marriages (Krishnan 2012).

Thanks to its complex nature the matrimonial decision in India, which has great cultural importance, has stimulated the rise of a large thriving industry of computer assisted matchmaking services catering to the millions of Indians searching for suitable spouses. This phenomenon, in turn, has attracted the interest of a variety of disciplinarians, including information scientists and social scientists.

This chapter's focus is sociological: it concerns the way the computer has been harnessed to assist both an ancient custom of arranged marriage among Hindus and the special occupational group known as matchmakers. The principal argument is that computer assisted matchmaking, thanks to the computer's virtually unlimited memory, improves the chances that the marriage contracted by a couple utilizing the service will be durable and happy because it offers the possibility for fine grained analysis.

From a sociological standpoint, it is maintained here that Indian matchmaking and medical diag-

nosis are fundamentally similar phenomena in that both are the result of non-random, non-rational processes that can be efficiently analyzed using *the garbage can model* of Cohen, March and Olsen, as modified by Zeldenrust (1990) and Fisher (2005). The model itself is a kind of dynamic input-output model that emphasizes flows into and out of the "garbage can" and storage within the "garbage can." Since its development in the early 1970s the *garbage can model* has been applied to study "decision making in organizational anarchies" (1972) and government planning (Kingdon, 1984); and in the modified form employed here it has been used to study research problem choices of scientific research teams in the Netherlands (1990) and in the United States and Canada (2005); and to study how to improve medical diagnosis (2014).

Although this chapter focuses on India, some conclusions may apply to other societies where arranged marriages also occur: in Japan (see Blood, 1967), among European royalty from the Middle Ages onward, (see, e.g. Harris, 1989); and among such groups as the *haridim* (ultra pious Jews). Elsewhere, e.g. among the wealthiest families in the United States, elements of arranged marriage survive in such traditions as debutante balls whose purpose is to enhance the probability that the eligible children of the wealthy elite meet and fall in love with suitable mates, i.e. eligible singles from "good" families. However, as Krishnan points out, in India, the tradition of arranging marriages has survived the homogenization of culture of the modern era (exemplified by the popularity of "pizza, burgers, denim and rock music in India as in Europe and North America") with the result that "in most Indian communities" people

feel “the need to conform to traditional marital practices” (p.18).

This chapter first briefly considers the complexity of the marriage decision as a consequence of constraints that must be satisfied, especially as it bears on the variety of data to be collected and analyzed. In India, the first constraint is that the marriage ceremony be performed as required by the tenets of the Hindu religion. This can be hugely expensive. According to Yee (2008), “the ceremonies are very colorful, and celebrations of the nuptials may extend for several days.”

Another constraint is the cost in time spent on the search for a suitable mate. Neither the family of the person searching for a mate for their eligible offspring nor the prospective bride (or groom) want a long drawn out search. Therefore, people seeking the services of a matchmaker or a computer assisted matchmaking service, will insist on a relatively limited group of highly desirable spouses, perhaps no more than six from whom to select the spouse. Unsurprisingly, given India’s billion plus population the computer matchmaking services have accumulated data about millions of marriage eligible individuals to cater to this demand.

A third constraint is that the negotiations between families can be similar in complexity to those between Indian “business groups”—somewhat akin to conglomerates or loosely affiliated companies that share key personnel (e.g. senior managers or owners). The latter for instance engage in lengthy, complex negotiations arising from a desire to merge or coordinate in some manner (Khanna & Yafeh, 2015).. Given the constraints and the importance for families of both bride and groom of a suitable spouse for their progeny, if information scientists can adequately address the technical problems of collecting, storing, and analyzing data on tens of millions of potential mates, it stands to reason computer assistance would be popular among marriage minded Indians.

How can *the garbage can model* illuminate the dynamics of the computer assisted arranged marriage in India? The model’s critical feature

relates to arriving at decisions based on imperfect and incomplete information in a nonrandom non-rational process: selection of a mate as a key societal decision to assure the replacement of deceased members of society.

H

BACKGROUND

What are the essential features of the decision to marry in the Indian context? First, without any slight intended to the many varieties of relationships among people, this chapter defines marriage as the union of a man and a woman with the intention of procreating and rearing children.

Selecting a mate given this intention becomes a non-rational decision made under conditions of imperfect information because the sexual compatibility necessary to procreate is unknown until conception has occurred. Selecting a mate in this context is also a non-random decision. Whether the decision to marry is preceded by rational calculation of the decision maker(s) or “chemistry,” the choice is definitely not random or probabilistic (though perhaps it could be modeled stochastically). It is socially patterned or cultural in a broadly understood way because the criteria of choice reflect societal standards of what is desirable in a mate etc. Finally, except perhaps in isolated cases it is not the decision of only the individuals who are to be married but of the organizational unit—the family, or more accurately, the families (a collectivity of organizations)—of the people to be married.

Krishnan illustrates this critical point noting that in her own case her “grandparents’ alliance was arranged solely by the family patriarchs.” The marriage of Krishnan’s parents “was initiated by the family elders but was approved by both of the [people to be wed]” while Krishnan herself and her future husband “initiated their relationship themselves and later received approval from both sets of parents.

As Krishnan points out, the participation of all stakeholders in the decision to marry even

when the romantic relationship is initiated by the people to be married has persisted over a long time, thus suggesting that marriage, beyond replacing members of a society, has other societal functions in India as indicated by Prakasa and Rao (1979) cited in Krishnan:

1. Maintain the social stratification system.
2. Give parents control over family members.
3. Enhance the probability of preserving the ancestral line.
4. Allow for the consolidation and extension of family property.

One further pertinent observation: while the uncertainty inherent in the decision to marry is never eliminated, the importance to the organizational units (i.e., the families of the marriageable individuals) of this decision is a strong inducement for them to seek specialized assistance in identifying suitable mates and perhaps negotiating the best terms possible for acquiring these mates for their progeny. In ancient times and continuing into the present the families in India (and elsewhere) would turn to a matchmaker who would gather information about potential mates for consideration by the family elders. Nowadays, that same role performed by a machine assisted matchmaking service—available from many companies in India—allows users to upload a profile describing themselves and the desirable traits they are looking for in a marriage partner. Unlike *social network sites* the matchmaking services use a special software, typically proprietary, to match users to potential mates who have also uploaded their profiles and the traits they are looking for in a partner.

Krishnan reports that the “web-based” matrimonial services, (called “*matrimonial portals*”) became popular almost instantaneously. (Also see Goel [2006]; Jana [2000]; Pepper [2007]; Philip [2005]; Ramalingam and Nair [2006]; and Sharma [Ph.D. diss. 2006] referenced in Krishnan) She credits three forces for this: “cable television; several international companies that entered In-

dia as a result of India’s globalization policies in the 1990s” (also see Kulkarni [2005]); and “the prominent role of Indian software engineers ... in the Information Technology revolution and Silicon Valley.” Together they “deeply influenced people’s attitudes and behaviors and hastened the adoption of the Internet by “both Indians living overseas and in India” Krishnan says, citing Shrama (2006). Indeed, while the decision for most people to marry is not entirely in the hands of family elders (as in ancient India and perhaps among the most traditional segments of society in India today), their involvement in the decision makes the choice of mate *a social fact* (Durkheim, 1982) *requiring explanation by sociological theories*.

MAIN FOCUS

In the following two sections first the theoretical model is presented and then how it applies to the issue of computer assisted matrimonial services is demonstrated.

a. The Garbage Can Model

The *garbage can model* which addresses *choices* in conditions of uncertainty (and indeed as shown above the decision to marry fits that description) seems promising. Nonrandom, non-rational actions are basically *choices*, which cannot be addressed by *utilitarian* approaches as they require perfect *information*.

The *garbage can model* accommodates elements of uncertainty, mainly random and stochastic events or inputs, involving actions and elements that may lack rational basis. The decision elements, notably problems, solutions, participants, settings and choice situations, pour into the organizational garbage can haphazardly (Miller and Wilson [(2006)]).

Zeldenrust (1990) emphasized that a decision (in his case a research problem choice) made in this environment of imperfect information has among its characteristics, that it results from a fortuitous

confluence of factors. That decision is a highly contextual event, depending substantially on the patterns of flows in the several streams. Problems may have more solutions; or fewer solutions may apply to more problems; or problems and solutions may emerge, or disappear, or become refined or redefined over time (an evolutionary process). And he noted that adopted solutions may not even solve a problem at hand.

The process of reaching a decision creates an *evolutionary trajectory* which becomes modified by the addition of informational items that may reflect uncertainties, opinions, *cultural patterning*, and, can themselves be subject to a cluster of constraints which are legal, situational, political, social, and psychological. Where the *garbage can model* works a confluence brings a decision-- perhaps unforeseen-- and which may not solve the problem to which it is attached. Furthermore, it may reflect politics, a certain amount of bargaining, and even a partial rational analysis (Mohr [1976]). The *garbage can model* downplays these emphasizing instead the *processes of going, coming and waiting*. For this seemingly chaotic situation to exist an uncoupling of the means and ends of decisions making are needed (Miller and Wilson referencing Weick [1976]). The uncoupling of process streams permits solutions to seek problems and vice versa.

The key modification of the *garbage can model* needed to apply it to a match--a choice by two respective actors or more to unite an eligible man and woman in marriage--is in the basic assumptions that flows are loosely coupled or uncoupled. Zeldenrust says there may be a *systematic coupling* in investigated cases. One or more flows may be *stable* or *consistent*. On occasion, the flow of problems may consist of just one, stable, consistent problem. Some choices may 'constrain or enable subsequent choices' Thus, as Fisher and Fisher (2014) note there may be "more stability, logic, or consistency" in decisions than foreseen by Cohen, March, and Olsen.

Beyond any necessary relaxing of assumptions about the coupling of flows if a *garbage*

can model is applied to a particular situation it is also necessary to have: (1) "choice arenas" such as places where families can go to get professional assistance in the hunt for a mate (these places may exist only in cyberspace); and (2) streams independent of or only loosely coupled to each other. One stream must be a demand stream (e.g. for treatment of the illness in the case of medical diagnostics or lack of a suitable mate in the case of matchmaking); another might be a solutions stream (knowledge of disease sufficient for a treatment protocol to be possible or a data base sufficiently large and diverse of possible mates for the matchmaker).

Constraints, individual or clustered, have either their own streams *or* become mathematical boundary conditions. Zeldenrust lists two main properties of constraints: *robustness* (can a constraint be overcome and [if yes] at what cost?); and, *specificity* (how well defined are they?; and also level, with reference to quality criteria, "how high is the standard?").

Only if *all the streams link* (an evolutionary threshold criterion) will a match emerge. In the case of a marriage the model says it emerges only if all the constraints are satisfied *and* the solution indeed meets the demand. This assumes that the demand has neither disappeared nor changed. In the arranged marriage context a changed demand requires a new potential candidate for a match which becomes final only by meeting the demand and satisfying all the constraints. This final result may in fact be the first of the conjectured tentative choices, or a later one, or altogether different from the set originally considered by the matchmaker. It may change if another match maker has entered the picture and applied a different set of constraints and solution streams. In the medical context, Sadegh-Zadeh (1982) has discussed this issue at length noting that uncertainty permeates even a diagnostic statement as when a physician informs the patient of his opinion in carefully couched language, e.g. 'I believe that' Or 'I consider it possible that'

b. Characteristics of the Matchmaking Process

In the matchmaking process as defined here it is assumed that the two people to be joined in marriage are both legally adults. This is quite different from the betrothal of underage children—a situation in which matchmaking often occurred in ancient India and still may occur in many cultures. As Krishnan deftly puts it, “because people in ancient times married very young, it made sense for the parents to make the decision to choose their children’s life partner. The decisions of the elders also were considered significant because of the newly-wed couple’s lack of physical or psychological resources (Bhagat, 2002).

In the case of two adults of childbearing age, as Krishnan remarks, “most people insist on interacting, meeting, or even courting before marriage.” It is this situation that underpins the process of computer assisted matchmaking.

In matchmaking, the matchmaker has gathered information about possible mates from other families to share with a client. It is advantageous to both client and matchmaker to have a huge data base of prospective mates because someone seeking a mate is likelier to be encouraged to seek a mate if they believe the odds of finding a mate are favorable. And the larger the pool of marriageable members of the opposite sex, especially if a great deal of pertinent data exists for all members of the pool, the more favorable the odds will seem to the client. In India, as Krishnan notes, certain attributes are likely to appear in the files of the matchmaker services: “age, education, salary, physical characteristics (height, weight, complexion), religion, community, personality attributes, and interests.” This information not only is provided about the potential client and the desirable match for that individual. Therefore, when finding a match, the matchmaker will exclude from the pool of potential matches for the client anyone who desire characteristics the matchmaker’s client does not have. For instance, if the potential match requires a Brahmin and the

client is not, that potential match will be excluded from the client’s initial list.

Some critics of match making worry that match making limits social mobility because people of higher status will decline to meet and court people of a lower social status. But that concern while not entirely unfounded is probably exaggerated. The reason is that the initial pool of potential mates may be too small when the client has extremely demanding sets of criteria. (How many eligible billionaires who have Hollywood --or “Bollywood”-- good looks are there likely to be)? In India, according to Krishnan, “fastidious” clients may find their search for a mate fruitless.

But mistakes of the other sort—not being demanding enough—also are probably discouraged by the matchmaker. The client who is not demanding enough will find the initial pool perhaps too large and the client will probably not meet and court the best possible future mate. It is to the matchmaker’s benefit—and perhaps the client’s as well-- if the client pool is neither too large nor too small. Probably handing a list of four to six or seven potential matches to the client is ideal.

Returning to the analogy of the matchmaking as a form of diagnosis consider now a fictitious (but plausible) example.

Dr. Indira Singh is a professional woman of Indian ancestry who has worked for a number of years in Antarctica as a biological scientist studying survival of organisms in extreme environments. She is in her late twenties and decides she really would like to be a wife and mother. She also would prefer a husband of her ethnicity and social status etc. However, in her professional circle she has not met men that she feels are right for her. To help her, she contacts a relative in India who arranges to initiate a search for a suitable mate through a matrimonial service. She agrees to spend time in India meeting possible mates generated by the matchmaking service.

The matchmaking service provides her a list of half a dozen possible mates and she goes out on dates with them. She is mildly interested in one of them but he does not reciprocate her interest.

Discouraged she returns to the United States where she has a good job with a university. During her first weeks on campus she meets and becomes romantically involved with a Jewish physicist. He is fairly religious and while he is attracted to her he insists his wife must raise their children in his faith. After consulting friends and professional people she trusts she agrees that she will convert to Judaism and raise their children in her husband's faith. Once that issue is resolved he proposes and they marry.

The example should make clear that the process of arriving at the final outcome is one of "trial and error." Laor and Agassi (1990) in their work on medical diagnostics acknowledge a disjunction between the perception of diagnosis as an initial activity and the reality of the activity. They comment that while the diagnostic process is supposedly confined to initial clinical diagnostic encounters, in more elaborate cases the process includes laboratory examinations of samples and specimens, and that may further elaborate into patient hospitalization. At that point the process is usually no longer viewed as merely diagnostic by most people, because it has become more complicated as well as more costly. This has occurred in the given example with the evolution of Dr. Singh's findings about the relationships she encountered.

First, Dr. Singh had the feeling that "something is wrong" and she further concluded that her life was incomplete, and therefore she needed a mate. Second, she felt that available help would be effective for resolving the problem. In the Indian culture, Krishnan reports, the matchmaker role has been institutionalized for millennia and therefore for the specific situation in the example matchmakers are likewise granted permission to collect information and, based on the tentative diagnosis of the client's need, offer a "treatment plan" that consists of a list(s) of suitable mates for the client.

Third, the matchmaker help did not immediately prove effective. The lonely scientist found that the initial "treatment" --the first list of "potential

mates" from the professional matchmaker in India-- did not yield a suitable match. She needed to generate a new list of acceptable mates who were likely to find her attractive.

Finally, her search was successful, albeit without the matchmaker's assistance. To use the medical analogy a diagnosis—the correct one—far from being the first step in effective treatment was the *final step* after various failed treatments in response to earlier tentative diagnoses.

Can Matchmaking Be Improved?

Economists looking at computer assisted match-making have offered some ideas for improving it (Mims, 2016). One of their ideas, "create a market that is 'thick' {i.e.} a market that has a lot of people seeking to link up" is certainly worthwhile. The suggestion is especially germane to the American market, more so certainly than to the Indian market which has been the subject of most of the commentary in this paper because the use of a middleman is widely accepted in Indian culture but rather novel in the United States.

While a bigger data base clearly is advantageous, equally important in finding a suitable match is that the list of candidates is based on high quality data derived from a well designed questionnaire/interview protocol. The aim is a pool that is the result of a fine grained analysis.

Another interesting idea that may not prove practical has been suggested by "{Paul} Oyer, a Stanford University economist." He argues the key to avoiding 'romantic unemployment' is to use "cost-benefit analysis," a highly technical form of analysis that few people outside that discipline have the time and interest to master.

Krishnan (2016) told the author that in India, faced with the possibility of having to choose between someone who does not meet their standards and "romantic unemployment," dissatisfied clients will either ask the matrimonial service to generate a new list or go to a rival matrimonial service for help because "settling for a mate is now considered an unwanted outcome" among users

of Indian matrimonial services. She added that this extra expenditure of effort spent on searching for an ideal match may be a consequence of the matrimonial services' being too successful in selling the concept of the online match service "Online databases give the illusion of infinite mate choices" and therefore customers "believe that they do not have to settle." A cost-benefit analysis is a last resort among consumers "wanting only benefits" from their online search.

Mims clearly understands that American consumers of match services also are loath to doing a formal cost-benefit analysis in their search for a suitable mate. However, he thinks American consumers, will not be as willing as Indian matrimonial service clients to continue their search. In a recent study of 1000 couples who met on [an American dating site] Mims reports within two months of joining women in these couples were 20% less picky on average" while "men in these couples were on average 12% more picky."

Mims unfortunately oversimplifies Oyer's position. A more nuanced description of Oyer's views might be called "finding undiscovered value" in a potential mate" that allows one to achieve a match. And sometimes the added expense of this research is justified by the return on investment from a superior match.

Consider the following case of a young woman scientist who in using an American matchmaking service finds two possible mates. They have overall scores that make them a toss-up in regard to choosing between the candidate with undiscovered or hidden value and being flexible enough to settle.

One is a good looking fellow who works with his hands, makes a decent living, but likes to hang out with the boys on Friday nights. Invariably, this likable fellow gets drunk while out with the boys and then either sleeps most of the next day or is somewhat abusive to his mate after he returns home from a bout of drinking.

The other suitor is a well educated fellow, a bit dull but otherwise nice, who regrettably has a low paying job. However, he is ambitious to improve himself. Which of the two suitors would the woman pick? Neither of them is a star but this

chapter's argument would suggest that the ambitious if somewhat dull fellow is clearly preferable. He has unrecognized value (because he has ambitions to improve himself) whereas the good looking fellow who hangs out with the boys and drinks to excess is either overvalued or at least fully valued. His drinking threatens to undo a possible marriage because of his abusive behavior after he drinks and unwillingness to give up his Friday nights out with his friends. This fictitious case is loosely based on people known to the author either because they are in his circle or are related to people in his circle of acquaintances. However, the aim here is to have the reader not lose sight of the point that settling may not yield results equivalent to benefit-cost analysis. On the other hand, for young men/women to do even a crude benefit-cost analysis may require a level of judgment and maturity that they may lack simply because they have too little experience in living. To highlight the superior choice the matchmaking service may need to intervene tactfully to highlight the differences between two candidates that the client cannot decide between.

CONCLUSION

Computerization has been helpful in making arranged marriage in India more satisfactory for all stakeholders by expanding the range of mates from whom a marriageable individual can choose and by allowing more fine grained analysis of the assets and liabilities any potential mate brings to the union. Thus a more informed decision is possible for all stakeholders. The author does not see any merit in the argument that the innovative use of computers to help select potential mates is more inherently supportive of the caste system than the old way of selecting a suitable spouse. The wealth of information the computerized search can provide enhances the potential of identifying someone as a mate with offsetting desirable traits and "undiscovered" value compared to the traditional way of selecting a mate in an arranged marriage.

FUTURE RESEARCH DIRECTIONS

Social science has developed a number of middle range theories that have demonstrated applicability across the traditional specialties and disciplines within the field. Notable among these middle range theories are the “garbage can model of organizational behavior” and coalition theory as well as such social psychological theories as the theory of cognitive dissonance, the Hochbaum-Huntington model of political mobilization, reference group theory to name just a few. These theories are breaking down traditional disciplinary classifications and substituting new ones including chaos theory, organization studies and so on. The present paper is one of a planned series on how technological change is affecting traditional work such as medical diagnosis, decisions to marry, etc. and how new models of social behavior can improve both our understanding of these changes and their efficacy for enhancing the wellbeing of society and its members.

KEY TERMS AND DEFINITIONS

Computer Assisted Diagnosis: A (tentative) conclusion or assumption which identifies the pathology represented by a patient’s (client’s) inquiry, particular set of symptoms, or complaints that has been reached with the assistance of a computer through the use of special (usually proprietary) software.

Confluence: As used in the “garbage can model” the intersection of various information streams at some critical point which enables one to proceed preferentially along a given informational evolutionary trajectory to the final diagnosis. Also referred to as a “linkage”.

Cultural Patterning: A behavior related to traditions, group social interactions and influences, and associated factors which do not necessarily have a scientific or nonrandom basis.

Diagnosis: A conclusion or assumption which identifies the pathology represented by a patient’s inquiry, particular set of symptoms, or complaints. As used in the Fisher=Zeldenrust version of the “Garbage Can Model” it refers to the final diagnosis of the problem as indicated by the fact the patient responded well to the treatment ordered based on the tentative diagnosis or the client was successfully matched to a potential marriage partner.

Evolutionary Trajectory: A vector which tracks the information inputs to the diagnostic process for a particular conjecture diagnosis until a final decision is made as to whether this particular conjecture diagnosis is accepted or rejected.

Garbage Can Model: A group of closely related theoretical models that analyze decisions under conditions of uncertainty. Originally developed by M. D. Cohen, J. G. March, and J. P. Olsen to analyze “organized anarchies”. These models make certain similar assumptions about the specific cases under consideration including that the problems and solutions are either “uncoupled” or “loosely coupled.”

Matrimonial Portals/Websites: Portals or websites designed for the sole purpose of finding a marriage partner. Similar to dating sites, these websites also feature users (clients) uploading their profiles onto a database and using various search criteria to find potential partners.

Social Networking Site: An online place where a user creates a profile and builds a personal network with other users. Although this can be used to find a marriage partner, it is more general and does not use a special proprietary software to match the user to other potential partners.

Creative Collaborative Virtual Environments

Luís Eustáquio

Universidade do Porto, Portugal

Catarina Carneiro de Sousa

Polytechnic Institute of Viseu, Portugal

INTRODUCTION

This article offers a definition of Creative Collaborative Virtual Environments (CCVEs), concerning models of collaborative and distributed creation in online virtual communities. Necessary affordances to enable a CCVE are described, and their importance is evidenced in the context of co-creation of content, using art practice as an example. This definition benefits a continued development and use of virtual worlds, as platforms for new collaborative models.

A CCVE is grounded on three key affordances: creation, collaboration, and distribution. These relate not only to the technical, but also to the social layers of virtual online communities.

Shared creativity and distributed authorship are approached as examples of specific dynamics rooted upon those three elements. Because the communities emerging from this type of creative flux provide fertile ground for the advancement of critical research on collaboration and creation in cyberspace, examples of multiple configurations are discussed, regarding the use of networks, technologies and participation frameworks.

Trough this definition, the authors propose to define models of collaborative and distributed creation in virtual online communities. Networked collectives of different practices and practitioners are discussed, across various virtual spaces, as examples of such models. Second Life (SL) is analyzed as a typical instance of a CCVE, since it

currently presents the most accessible and integral approximation to this concept.

The discussion supported by these observations ultimately demonstrates how the co-creation of new content and meaning takes place through collaborative practices in virtual worlds, and how Creative Collaborative Virtual Environments widen the gamut of communicative and creative agency in digital communities.

BACKGROUND

Virtual worlds are commonly referred to in literature as the Metaverse, a term coined by novelist Neal Stephenson in his seminal fiction *Snow Crash*. There, the Metaverse is an immersive virtual 3D world, where people interact through their digital manifestations, avatars. While the term has been broadly applied to the entire collective online space, it is specifically connected with simulated worlds in virtual 3D space. Spatiality is the most distinguishing feature of virtual worlds, as they provide an immersive experience where one moves across a (virtually) infinite, simulated world, rather than a two-dimensional metaphor of a desk with folders and a trash bin. Tom Boellstorff (2008) advances three fundamental properties of virtual worlds: they are places, inhabited by people, and enabled by networked technologies.

Virtual worlds are also often called Collaborative Virtual Environments (CVEs). Churchill,

Snowdon & Munro describe them as locations for action and interaction (Churchill, Snowdon, & Munro, 2001), virtual spaces where people can meet and interact with other people, agents and virtual objects. CVEs promote users from spectators to active participants in the Metaverse, able to engage each other and the virtual environment.

THE CREATIVE APPROACH TO CVE

A collaborative space enables dialogue and exchanges between users, but is not required to enable content creation at its core. On the other hand, a creative environment does not strictly require online collaborative features to afford creativity. As noted by Lévy (2001), the distinction between read-only and read/write virtual worlds is not an opposition. Many virtual environments are able to digest “offline” processes to some extent, importing or exporting content. Others may allow some degree of self-expression, through limited customization options. However, limited presets do not empower users to create or reinvent their own virtual world. To achieve this potential, users must be able to create, modify, transform and redistribute media assets that constitute the very fabric of the virtual world: notably, audiovisual components (including 3D data, if applicable) and program code.

Users must also be able to employ such tools according to their own policies and methodologies, regarding aspects such as creative process and media rights management. Virtual worlds can be complemented by other platforms, such as forums and social networks (Al-Jarrah & Pontelli, 2014; Ferguson, 2011; Kohler, Fueller, Matzler, & Stieger, 2011), but in-world resources for creation, communication and asset distribution, enable a CVE to become a platform for works of flow and process. CVEs also remediate specific features from other platforms. This includes live and relayed text messaging, video streaming and file sharing. They also introduce features unique to virtual worlds, such as live visual expressive-

ness through avatars, and shared 3D spaces. These features promote users from spectators to active participants, but they still don’t afford users creative control over the virtual world they inhabit.

CCVE AFFORDANCES

For a CVE to be considered a CCVE, it must afford creative input and action. For creativity to be considered collaborative, users must be able to distribute and modify in-world content. This requires built-in platform features for collaborative creation, modification and distribution of content, to a degree that empowers users to collectively shape the virtual world itself.

Necessary features to enable such affordances are described in the following sections.

Creation

The first key affordance is creation. For a virtual environment to be considered creative, users must be able to partake in the making of the world itself. The range of creative input may vary according to a platform’s specific features: a wider range of creative options increases creative possibilities. However, platforms easily become overly complex, making it difficult for average users to master these creative possibilities, effectively professionalizing the creative activity. A sound balance between creative possibility and tool complexity is hard to achieve, and this is often remedied with content upload. Complex content can be built externally, allowing the platform itself to remain more accessible. The ability to create content can thus be split between building within the CCVE platform, and/or uploading content built using external resources. Table 1 offers examples of features a CCVE might offer within this framework.

Collaboration

Another core affordance of CCVEs is the possibility of creative collaboration. Collaborative

Table 1. Affordances and related features for creation in CCVEs

Creation		
	Affordances	Features
Within the virtual world	Content creation	Create new 3D objects; map textures; edit landscape and environment; trigger sound reproduction; write new code to change behaviour of world, objects and avatars.
	Content modification	Tools to modify settings and properties of existing avatars, terrain, objects, audio and visual media, environment and dynamic behaviours.
Outside the virtual world	Import content	Allow user to upload data from local storage to virtual world server; accept input of standard file formats for text (including code), images, video, 3D objects, and sound.
	Export content	Allow user to transfer data from server inventory to local storage; produce output in standard formats for text, images, video, 3D objects and sound.

activities require actions of a user to be perceived by other participants, for there to be interaction between users. This kind of interaction implies negotiation. Churchill and Snowdon's (1998) research on negotiation processes advances important aspects required for successful collaborative actions in mediated environments. First, one needs to understand the transition between shared and individual actions. This requires explicit and tacit communication, as well as the ability to perceive what is being done and what has been done. Flexible and multiple viewpoints are also important in shared activities. A second aspect is multilingual text display. A shared context is probably the most important, requiring shared environment, shared artefacts, but also shared knowledge or shared understandings. Equally important is the awareness of others, the sense of shared activities and the ability to communicate about them, verbally and nonverbally. Churchill and Snowdon refer

studies which suggest facial expression, body posture and gesture carry 60% to 90% of information communicated. This is a known challenge faced by current existing virtual worlds: although there are built-in gestures, and it is possible to upload animations to move an avatar in intentional ways, both lack the spontaneity required for casual communication¹.

Table 2 articulates aspects highlighted by Churchill and Snowdon (1998), as co-creative affordances, associated with specific features required for a platform to enable them.

Distribution

Distribution is the third key affordance of CCVEs, extruding the circle of creation and collaboration to a sphere of action and meaning, defined by a multitude of points on stems connecting it to as many other spheres. This image represents the inbound and outbound nature of such connections.

Table 2. Affordances and related features for collaboration in CCVEs

Collaboration	
Affordances	Features
Communication	Channels for verbal communication, written or spoken, relayed or in real-time. Forms of nonverbal communication, such as facial and body expression.
Awareness of others	Perceive and observe relative position and actions of others in virtual space; feel the impact of other's actions.
Shared context	Ability to share real-time experience of the same location and environment.
Flexible viewpoints	Viewpoint control: travel, pan, tilt, rotate, zoom.

Table 3. Affordances and related features for collaboration in CCVEs

Distribution	
Affordances	Features
Exchange content with other users	Transfer and save files: tools to give/sell/lend, and store content.
Present content in shared space	Render objects; produce sound; performative action.
Peer property mode	Copy and save content from shared spaces; shared file storage.

Distribution applies to all kinds of artefacts and experiences in virtual worlds, multiplied by the number of users who experience them. This entails enabling users to: store and exchange files; render media and objects in common space, including performative action; save assets from the environment; share ownership of and access to media assets.

CCVEs thus extend participation beyond observation, allowing peer to peer collaboration. This unlocks a transformative potential not limited to technical features. Rather, it configures new programs of governance, modes of production and ownership regimes. Users are able to replace a “market exchange value” with a “use-value for a community of users”, creating a “peer property mode” fundamentally different from private or public property (Bauwens, 2006, p. 33) as it enables direct and collective governance.

Distribution also concerns authorship, as manifestations of creation in virtual worlds inevitably draw from labor in previous connections. Aggregations of multiple connections constitute scenarios of distributed creativity and authorship, converging towards Axel Bruns’ (2007) concept of produsage, which describes “projects which harness the creativity of a large range of participants to build on and extend upon an existing pool of artistic material” (Bruns, 2010, p. 1). Produsage is prevalent across online creative communities², where massively distributed bodies of work emerge through processes in which practitioners shift back and forth from producers to users, originating hybrid roles (Bruns & Schmidt, 2010, p. 3) within a creative process where artefacts and their

production cycles are open-ended, repositioning users as co-creators and active participants (Bishop, 2012). Table 3 presents a summary of affordances for creative distribution, and corresponding necessary features.

SHARED CREATIVITY

CCVE affordances lead to new creation/collaboration models, characterized by Catarina Carneiro de Sousa (2013, 2015) as shared creativity, a creative input distributed by several creators, processed in different timeframes, across different places and through different approaches, enabling a fluid creative stream. These variables work together in three distinct modes: collective creativity, collaborative creativity, and distributed creativity.

Collective Creativity

This mode draws from collective effort, asynchronously or through simultaneous participation. Each participant’s contribution is mostly indistinguishable, making all participants equally responsible and creditable. This modality does not exclude other significant aspects of collectivity, as it simply designates a workflow where all participants form a singular creative entity. In a cellular structure, an egalitarian basis provides greater chance of success when individuals waive their personal mark to benefit collective authorship (CAE, 2002). Collective creativity is then a process undertaken by a group of creative partners, in a profound level of intimacy.

Collaborative Creativity

As an “open-ended concept”, collaboration “becomes an umbrella term for the diverse working methods that require more than one participant” (Lind, 2007, p. 17). Collaborative creation does not strictly deal with the collaborative aspect, for it provides a rather wide frame of reference, regarding organization methods and creative process. Instead, collaborative creation designates a process in which participants create together, but each individual authorial mark can be variably discernible, as the borders of each contribution blend into a collectively authored outcome. This process often takes place as a conversation, where each participation is a creative response to earlier contributions.

Distributed Creativity

Distributed authorship was initially proposed in 1986, by digital art pioneer Roy Ascott. This concept emerged from *La Plissure du Texte: A Planetary Fairytale (LPDT)*, a collaborative, remote authoring project, launched by Ascott in 1983. Axel Bruns (2010) employed this concept to describe internet-augmented creative processes. Bruns specifically addresses projects comprising a considerable number of participants, contributing to a common pool of creative resources and artistic production. Here, however, participants act individually, taking their own steps along the creative process, configuring a modality of distributed creation (Bruns 2010, p. 1).

INSTANCES OF CCVE

The definition of CCVE refers exclusively to online virtual worlds, therefore excluding collaborative platforms such as text-based forums, and virtual environments such as single-player games. Not all online virtual worlds are implicitly creative and collaborative, and not all are networked in freeform configurations. Even when a virtual

environment offers creative and collaborative features, their design and operation may hinder in-world co-creation, and freeform collaboration. A CCVE thus requires more than the sum of these parts, to afford users actual control over modes of collaborative creation.

Virtual worlds like SL or OS grids offer the closest available approximation to the CCVE definition³, as they meet most requirements previously described. Both offer its users real-time in-world interaction, through avatars, in a spatial environment, inhabited by users, connected by a network. Together with tools to reshape every aspect of the virtual world from the ground up, including the ground itself, this allows synchronous co-creation. These features thus enable in-world creation, collaboration and distribution, making this collaborative virtual world also a creative one. These platforms embrace internal forms of collaboration, by providing tools for communication and sharing. Public and private chatrooms enable both real-time (conversational) and asynchronous (message log) verbal communication between users. Embedded automated translators, albeit somewhat limited, facilitate conversations between different languages. Every user can store various media types: images, texts, sounds, 3D objects and scripting code. These items can be copied and sent to other users, or placed on virtual space to be picked up by others. Collaboration using external resources is equally possible, by importing rich media into the virtual world. Through built-in features or alternative techniques, users can extract and store audiovisual results from the virtual world, for documentation or further work. Thus, tangible and virtual world are not separate networks but closely connected, heterogeneous nodes of a rhizome, enabling workflows from global community to virtual environment to physical museum, for example.

Actions in SL and OS grids are not limited to preset contents or programs of action. Beyond “inhabiting” and perusing virtual spaces and goods, residents can create, modify and distribute new artefacts, texts, topologies, and narratives. Not be-

ing limited to preset inventories and geographies, these platforms put the creation of impossible objects and dream environments within reach of any user. This combination of creative possibility and sharing ability configures a wider range of participatory aesthetical experiences than is possible in games such as *World of Warcraft* or *League of Legends*, as the ability to create all aspects of a virtual world from the ground up is exponentially more empowering than incremental customization or orchestrated theatricality. Jennifer Novak-Leonard and Alan Brown (2011) propose a framework for modalities of artistic participation which comprises five levels: Ambient Participation describes chance encounters with artworks; Observational Participation describes passive attendance of events; Curatorial Participation includes selecting and relating artworks; Interpretive Participation describes performative self-expression; and finally, Inventive Participation “engages the mind, body and spirit in an act of artistic creation that is unique and idiosyncratic” (Novak-Leonard & Brown, 2011). In publicly accessible CVEs, one can find users whose activity can easily fit most of these categories. However, SL (and OpenSim based equivalents) enables the full spectrum of modality in artistic participation, through its specific combination of features, which cannot be said of most virtual platforms it is usually compared to, most notably mainstream multiplayer games. Creation and participation in SL is enabled by the technical realm, but fulfilled in the social realm. While most games implement interconnectivity for the purpose of joint action towards preset goals, SL configures a program without totality, driven by autonomy and an openness toward alterity (Lévy, 2001).

Meta_Body

Currently virtual worlds such as SL and OS grids are home to a prolific community of artists and art-driven spaces (Sousa & Eustáquio, 2015). The authors of this article are active members of this community, developing their projects within the

virtual artworld. This discussion will now turn to one such project, as an example of how virtual world features drive shared creative processes.

Meta_Body is an ongoing collaborative project, set in motion in SL by Meilo Minotaur (Sameiro Oliveira Martins’ avatar) and Author 2⁴, spanning several virtual and tangible environments since 2011.

As a first step, eighteen avatars were created and distributed with full permissions, to be freely duplicated, modified and redistributed by any willing participant. Derived creations could also be freely distributed. Each avatar included a text note, inviting residents to participate with derivative artworks in a tangible art exhibition. 120 derived works were initially selected for an exhibition in Austria⁵, including virtual photographs⁶ and machinima⁷.

A second edition started in 2012, titled Meta_Body II. Residents were invited to produce new avatars, derived from the Meta_Body set, which were then redistributed, again with full permissions. They were now collectively authored, built from parts of the original avatars from the first edition. The project achieved increased exposure and embraced an even wider range of participations⁸, of which Figure 1 provides an example.

In both editions, a unique virtual installation was built from the ground up, where one could enjoy a shared aesthetical experience. Meta_Body II encompassed the creation of four expansive landscapes, each with its own aesthetic character and nature, related to the avatars distributed there. Author 1⁵ developed soundscapes that changed dynamically as one moved across virtual space, adding immersiveness to the experience.

Meta_Body offers an opportunity to observe various phenomena within CCVEs. Retrieving concepts of produsage and peer to peer collaboration, one such phenomena is artistic creation as a collaborative process, set in motion by a community, within the context of decentralized co-creation of content. While popular social networks are valuable to spread awareness of projects and call for participations, CCVEs add

Figure 1. To the right, an avatar from Meta_Body phase I: Godiva, by CapCat Ragu and Meilo Minotaur. To the left, an avatar from phase II: Appointment in the garden, by Simotron Aquila.

new variables and mechanisms to this participatory context. These stem from a combination of three key factors mentioned earlier: creation, collaboration and distribution.

Meta_Body translates these practice values into a shared creative process, which comprises three approaches previously described: collective creation, distributed creation and collaborative creation. Collective creation is the process used in the construction of original avatars by Meilo Minotaur and Author 2⁵. Distributed creation describes how most participants entered the creation flow, building upon previous work and sharing derived output for further reinterpretation. Finally, collaborative creation is the process used with Author 1⁵ in creating soundscapes for the Meta_Body II virtual installation: while developed independently by a single author, the sounds inhabit virtual spaces without physically altering them, but strongly affecting their perception.

These modalities of shared creativity represent the variable “open-endedness” of cultural and creative expression in online participatory environments, in collaboration as a collection

of methods for working together (Lind, 2007). Through these processes, “communicative practices offered online actualize, enact, and thereby reshape specific cultural ideals”(Langlois, 2013, p. 92). By selecting previous work to deconstruct, reinterpret, act and build upon, participants employ the platform’s communicative agency to strengthen or weaken connections in a semantic network, changing its shape and dynamics from within collective practice. Figure 2 presents a practical example.

FUTURE RESEARCH DIRECTIONS

New platforms and communities continue to emerge, industrial and academic research in the field is blooming, and multinationals compete to set the standard platform for virtual reality. As they mature and mutate, virtual worlds operate on rapidly changing software and hardware. Greater computational power enables finer detail and fluid motion. Increased bandwidth enables complex environments to be shared online.

Figure 2. To the left: You see my inside, avatar from Meta_Body phase I. To the right, the alpha_tribe reinterpretation.

Experimental hardware research pursues more intuitive and expressive interfaces for humans. These factors amount to a considerable potential for the future of virtual worlds, where accessibility, immersion and ubiquity become possible goals. Numerous avenues for important research lie in this future, as new interaction paradigms entail new aesthetic experience modalities, and new organizational structures in virtual communities. These are relevant to artistic practice, collective and individual, but also to research in areas such as games, psychology, sociology, pedagogy, health and economy. For virtual worlds to remain open, features to enable creative and collaborative affordances must be kept and expanded. The authors advance the concept of CCVE as a contribution toward such a future.

CONCLUSION

A Creative Collaborative Virtual Environment is a digital virtual environment, where a group of people can remotely interact and collaborate, asynchronously or in real time, in the creation, modification and distribution of media and content that shapes the virtual world itself. Expanded from Collaborative Virtual Environments (CVEs),

CCVEs exist in networked, computer-generated 3D spaces, simultaneously inhabited by various visitors (Boellstorf, 2008). Accessible as software platforms, they enable different levels of engagement and modalities of collaboration (Lind, 2007). CCVEs feature an enhanced creative dimension, through specific software features and affordances of creation, collaboration and distribution. These affordances enable rhizomatic formations of heterogeneous, non-hierarchical connections, accommodating variable origins and flows for creative practice (Deleuze & Guattari, 1987). This increased spectrum of communicative agency contributes to heightened senses of presence and copresence in virtual worlds, shaping new conditions for negotiation of action and meaning (Ijsselsteijn & Riva, 2003). Produsage (Bruns, 2007) enables various modes of collaboration as described by Sousa (2015), which demonstrate open-endedness in cultural and creative expression, through networks of decentralized communication and decision-making. Ultimately, CCVEs demonstrate how “networks of technologies, users, and social processes define and delineate specific modes of experiencing meaning” (Langlois, 2013, p. 103), by enabling co-creation of new content and meaning through collaborative practices in virtual worlds.

KEY TERMS AND DEFINITIONS

Affordance: The concept of affordance is somewhat variable across scientific areas. Its mutation from verb to noun occurs in Gibson's Theory of Affordances (Gibson, 1986), referring to environmental actionable properties, but ultimately designating relationships between environments and actors therein. Affordances have been ascribed a functional role in active cognition, in an attempt to deconstruct our perception of such relationships, as when Donald Norman (1999) discusses real versus perceived affordances in interface design. Currently, affordances are strongly related with interaction processes, designating a range of action possibilities (Xenakis & Arnellos, 2013) emerging from engagement between actor and environment or artifact.

Distributed Authorship: Term coined by Roy Ascott (2005) to describe interactive and remote

authoring. The same term was later used by Axel Bruns (2010) to refer to projects in which a large number of participants contribute to a common pool of artistic material.

Feature: Designates specific characteristics and programs of action, found in software, artefacts and processes. In this sense, a feature is understood to exist as part of a virtual object, a software application, or a workflow, irrespective of its employment by an actor in a given environment.

OpenSim: Open-source multi-user 3D application server, used to create digital environments enabled by network technologies, experienced through the use of avatars that represent the user in the environment, on multiple protocols. This software enables developers to create and customize virtual worlds, using their preference of technologies. These worlds can be hyperlinked with each other, using the Hypergrid as an additional resource (OpenSimulator, 2014).

Participation: Describes a user's level of engagement in a specific platform. This notion is borrowed from contemporary art theory, analyzing recent transformations in the role of the audience, from simple viewer to co-producer or participant (Bishop, 2012).

Produsage: Term coined by Axel Bruns (2007) to describe a work process where participants shift from users to producers and vice versa, originating a hybrid role in between, the produser.

Second Life (SL): Digital, multi-user, 3D world, enabled by network technologies, experienced through the use of avatars that represent the user in the environment. This world is entirely created by its residents.

ENDNOTES

- ¹ Emerging virtual worlds and associated hardware (some offering public Alpha versions, e.g. High Fidelity) may mitigate this problem in the future, through the use of motion capture devices and facial tracking software (Simonite, 2014).
- ² These communities span various platforms outside of virtual worlds, such as flickr (<https://www.flickr.com>) and DeviantART (<http://www.deviantart.com>).
- ³ Other virtual worlds and new hardware are currently emerging (e.g. High Fidelity, as mentioned before) with the potential to meet the requirements described.
- ⁴ Avatar and real name will be provided after blind peer review.
- ⁵ The 6th edition of All My Independent Women, curated by Carla Cruz. Since then, Meta_Body has integrated several other "real-world" exhibitions and festivals.
- ⁶ Still images captured from virtual worlds.
- ⁷ Videos captured from real-time rendering of virtual worlds.
- ⁸ Twenty-two creators built twenty-six new avatars, with participations from renowned metaverse artists, designers, and new residents, in their first exploration of Second Life and avatar building. Furthermore, residents continue to produce derivative work in multiple platforms,, beyond the initiators' tracking ability. Some of this work can be found at the Meta_Body Flickr Group, now encompassing more than a thousand works and 376 members (https://www.flickr.com/groups/meta_body/pool/).

Cyberbullying

Gilberto Marzano

Rezekne Academy of Technologies, Latvia

INTRODUCTION

Information and communication technology (ICT) plays a central role in contemporary society. Computers are affecting human life in a great deal in that they are essential in all life dimensions. An increasing number of things run by computers, while massive amount of multimedia materials circulate through the Internet, especially by smartphones. New technologies have thoroughly penetrated into the everyday life since not only affect science and business, but also leisure and interpersonal relationships.

The difference between contemporary and past epochs lies in that, nowadays, the reality includes both physical and virtual things as well as living and artificial agents.

One of the chief impacts of computer is on communication which has made a great leap forward thanks to the advances in networking and internet technologies. Today, one can connect with friends and family around the world as well as can deal with business anywhere and anytime.

Despite these changes, human nature remains the same and the people's evil behavior didn't change. Paradoxically, thanks to the Internet, cheaters may have at hand more ways to cheat and perpetrators dispose of new powerful means for harming and harassing their victims.

Cyberbullying is a new, alarming, and evil phenomenon closely connected with relational changes that new technologies are causing in our society.

Essentially, it consists in using the Internet to harass, threaten, and harm individuals who are the weakest and most vulnerable. Victims of cyberbullying are mightily children and adolescents. In fact, young people are immersed in new digital

technologies and use them without knowing their implications.

In the Internet world, it is meaningless to say that "children should be treated like children": information technology put absolutely on the same level adults and children. The difference between children toys that imitate adult objects, e.g. a tricycle and a bicycle or a pedal car and a motor car, doesn't work on the Web. There isn't the *Internet for children* and the *Internet for adults*. Both adults and children use the same devices, tools, and ways of communicating and interacting.

It is universally agreed that no responsible adult would give the car keys to a child or an armed gun. Even though, this is what an adult does when puts in the hands of children a smartphone with an active Internet connection without give them any advice about the cyber threats.

This chapter aims at presenting cyberbullying as a direct consequence of the social metamorphosis that, induced by the diffusion of the new technologies, endangers our security and exposes us to new actual threats. The following paragraphs illustrate the background of this evil phenomenon, then, specific aspects, such as cyberbullying diffusion, the difference between cyberbullying and traditional bullying, and the characteristic of cyberbullying, are discussed. Finally, some new emerging phenomena related to the sexual sphere, the so-called revenge pornography and the homophobic cyberbullying, are highlighted.

Background: Cyberspace Threats and Cyber Violence

As the real world, cyberspace is full of real dangers and pitfalls: cyber violence can produce similar effects as the real-world violence (Finn, 2004;

DOI: 10.4018/978-1-5225-2255-3.ch360

Figure 1. Lifetime Cyberbullying Victimization Rates (nine different studies 2007-2015)

Source: Cyberbullying Research Center¹

Temple et al., 2016). Furthermore, what in real life is blamed, such as gambling and pornography, in cyberspace is easily affordable. Cyberspace relative anonymity gives people the opportunity of accessing places where, in real life, decency and shame usually prevent them from frequenting. Anonymity is one of the crucial aspects of cyberspace which offers opportunities and, at the same time, exposes users to risks and threats.

At the moment, cyber violence is difficult to define and, as a results, its prevalence rates are largely unknown (Peterson & Densley, 2016).

Many forms of cyber violence correspond to traditional forms of aggressive behavior. Perpetrators of cyber violence are not a uniform group, but they share the characteristic of exploiting digital media as a powerful weapon to inflict real damages to their victims. This is the case of *cyberbullying*. This term refers to bullying through new technologies, especially the Internet and smartphones.

Cyberbullying is the most controversial form of cyber violence (Corcoran, Guckin & Prentice, 2015) and there is a vast literature on this issue that addresses the phenomenon from different points of view: that of victims, perpetrators, and

bystanders, that of educational institutions, that of legal measures, that of prevention, and so on. Many sites have been created by parents of children who, after being victims of cyberbullying, committed suicide or by associations that to combat the cyber violence.

Figure 1 shows data from a survey conducted by the *Cyberbullying Research Center* directed by two influential researchers on cyberbullying, Sameer Hinduja (Florida Atlantic University) and Justin Patchin (University of Wisconsin-Eau Claire).

In 2013, the results of a three year multi-disciplinary project which involved researchers from 28 countries of the European Union have been published (Smith & Steffgen, 2013). This project traced a demarcation line from the previous research, often too oriented to psychological interpretations of cyberbullying.

Many of the first cyberbullying interpretations were based on media reports. For obvious reasons, media emphasized cyberbullying extreme cases, this is, which culminated in the suicide, or the attempted suicide, of victims. Media continue to underline the toxic and suicidal consequences of harassment resulting from new technologies. But, this is a wrong assumption. A few years ago, Marr

and Field (2001) documented and analyzed some cases of suicide due bullying, and coined the term *bullycide*. Authors recognized in the UK at least 16 cases per year of evident and diagnosed bullycide, claiming that bullycides were much more since many of them were not considered as such by investigative authorities.

In the next paragraphs we focus on some essential aspects of cyberbullying: diffusion, definition, and peculiar characteristics.

Cyberbullying Diffusion

Cyberbullying is wide spreading globally: affects over 50% of young people of school age.

However, a few years ago, Olweus, the pioneer in the field of bullying prevention and creator of the Olweus Bullying Prevention Program ² (Olweus & Limber, 2010), claimed that cyber-bullying was an overestimated phenomenon. He argued that media often exaggerated about the cyberbullying diffusion and the first investigations in this field were scientifically poor (Olweus, 2012).

Under certain aspects, the Olweus's criticism was correct. Since the 2010s, the most of literature flourished around cyberbullying was not always based on large samples or on reliable statistical data. Indeed, due to the novelty of the phenomenon, many studies were not based on a common definition of cyberbullying and many researchers were brought to extend the sphere cyberbullying including all sort of malicious behavior. Olweus well underlined the defects of the first investigations on cyberbullying, which studied this phenomenon out of the general context of the traditional bullying and created the image of cyberbullies as young introverted adolescents, expert in computing, who, taking advantage of the Internet anonymity, discharge their frustrations harassing classmates. Early research on cyberbullying (*online bullying*) was often based on media reports of cyberbullying cases and some studies were not theoretically and methodologically rigorous (Hinduja & Patchin, 2012).

However, the diffusion of cyberbullying cannot be underestimated and a reductionist attitude is dangerous. Cyberbullying is really an alarming phenomenon considering two distinctive aspects. The first concerns the fact that the Internet is the primary means of socialization for young people. Adults usually use the Internet for working, buying items, paying bills, and similar things, whilst young people use it for staying in touch and communicating among them. The second aspect concerns the nature of the Internet, namely that its contents are accessible to all, or at least accessible to a large number of users, are not controllable, and not easy to delete. The "right to be forgotten" is a concept discussed and put into practice in the European Union since 2006; it concerns also the Internet contents and is matter of a legal debate around the world (Bartolini, & Siry, 2016). A recent survey indicated that, in the USA, 9 in 10 Americans want some form of the right to be forgotten.³

Despite the people interest, it is not easy to apply the right to be forgotten on the Web due to many technical problems. As a consequence of this, Internet contents remain, at moment, globally accessible, uncontrollable, and permanent.

Table 1 shows the common types of harassment practiced by cyberbullies.

Cyberbullying Definitions

A debate is ongoing about the definition of cyberbullying and the differences between cyberbullying and traditional forms of bullying (Thomas, Connor & Scott, 2015; Menesini et al 2012).

Some of the most cited definitions of cyberbullying are: ⁴

An aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself. (Smith, Mahdavi, Carvalho, Fisher, Russell & Tippett, 2008, p. 376).

Table 1. Common cyberbullying harassments

Types of Harassment	Description
Name-calling	The use of language to defame, demean or degrade individuals or groups
Flaming	Posting hostile and insulting messages to intentionally harass somebody
Exposure	Posting or forwarding of personal communication, images or video which contain sensitive personal information or are detrimental to an individual
Excluding	Cruelly excluding someone from an online group
Denigration	Sending, posting, or publishing cruel rumors, gossip and untrue statements about an individual to intentionally damage their reputation or friendships
Impersonation	Impersonating somebody to make unpopular online comments or creating fake profiles to offer defaming information
Image and video dissemination	Images and video are disseminated to humiliate and disparage an individual
Happy slapping	A victim is physically attacked or embarrassed in person and video or pictures of the incident are recorded and diffused
Tagging	Inappropriate images and texts are tagged so that hurtful information appears on victim timeline
Cyberstalking	Cyberstalking includes threats of harm, intimidation, and/or offensive comments sent through Information and Communications Technology channels
Threats	Threatening a victim by cell calls or messages
Blackmail	Personal information are used to obtain ransom payments

[cyberbullying is when someone] repeatedly makes fun of another person online or repeatedly picks on another person through e-mail or text messages or when someone posts something online about another person that they don't like. (Hinduja & Patchin, 2012, p. 540)

Cyberbullying involves the use of information and communication technologies

to support deliberate, repeated, and hostile behavior by an individual or group, that is intended to harm others.⁵

The above mentioned European project of 2013, after a thorough examination of bullying and cyberbullying characteristics concluded:

[...] there is a large agreement within the literature about the definition of cyberbullying based on the criteria of intentionality and power imbalance [...] A lower level of agreement characterizes the criterion of repetition: qualitative studies underlined it is very relevant and literature on general aggression is likely to stress this criterion of specific of bullying and therefore of cyberbullying. (Menesini et al., 2013, p. 33)

Bullying vs. Cyberbullying

The Norwegian researcher Olweus (1993) claimed that *intentional aggressiveness*, *repetitively*, and *power imbalance* are the three key components bullying.

The bullies' behavior is aggressive and intentionally designed to hurt others or their relationship, or even to frighten them. Bullying behavior often occurs without an apparent provocation.

Beran and Li (2005), referring to cyberbullying, used the expression "old wine in a new bottle". They claim that cyberbullying is a form of bullying people by using new technologies that bullies handle just as a tool to attack and harass their victims. For certain aspects, this position was a reaction to the idea of those researchers who argued that cyberbullying was a specific and completely new phenomenon.

The contiguity between bullying and cyberbullying seems confirmed by the data of numerous investigations (Ybarra & Mitchell, 2004; Beran & Li, 2008; Kowalski, Limber & Agatston, 2008; Perren, Dooley, Shaw, & Cross, 2010; Sourander et al., 2010; Del Rey, Elipe & Ortega-Ruiz, 2012).

Data shows that there is an overlapping (44%) between online victims and victims of physical aggressions in the real world. In particular, either Beran and Li or Kowalski and Limber found that about 60% of victims of bullying are also victims of cyberbullying. However, if 40% of victims are only bullied online, this means that cyberbullying also discloses an autonomous and specific nature. This aspect is indicative of the complexity of the problem and should be carefully considered to understand cyberbullying and prevent and combat it. The fact that cyberbullying occurs not only as a pure extension of bullying but also as something specific suggests that different prevention strategies should be designed for the different contexts.

Data from a German study (Riebel, Jaeger & Fischer, 2009) confirms that over 80% of cyberbullies are bullies in real life.

But what really is cyber-bullying?

The literature contains many definitions of cyber-bullying (Smith, Cowie, Olafsson & Liefvooghe, 2002; Patchin & Hinduja, 2006; Ybarra, Mitchell, Wolak & Finkelhor, 2006; Ybarra & Mitchell, 2007; Dooley, Pyżalski & Cross, 2009; Ortega-Ruiz & Núñez, 2012; Heirman & Walrave, 2012; Wachs, Wolf & Pan, 2012; Palladino, Nocentini & Menesini, 2012; Paul, Smith & Blumberg, 2012; Vandebosch, Beirens, D'Haese, Wegge & Pabian, 2012; Rodríguez-Franco et al., 2012).

Many researchers share the definition of cyberbullying by Kowalski and Limber (2007) who consider cyberbullying as a particular form of bullying through new media and new digital communication devices, such as mobile phones, e-mail, the Internet, social networks, web pages, chats, and blogs. Cyberbullies are depicted how individuals who threaten, terrorize, defame, humiliate, offend their victims at a distance, and use images, movies, e-mail, messages, and comments on the Internet to harass and harm their victims.

Cyberbullying Characteristics

Although traditional bullying and cyberbullying share many common characteristics, some distinctive features have been identified (Dooley, Pyżalski & Cross, 2009; Smith et al., 2008). Two are very relevant: the audience of the traditional bullying is formed of small groups of peers, whilst that of cyberbullies can be very vast and uncontrolled; furthermore, cyberbullies may be little aware or even completely unaware of the consequences of their evil actions.

Furthermore, there are some other elements which are exclusive of cyberbullying. One is due to the nature of technology and is the lack of control over it. For example, once a digital harmful content (sms, text, images or video) has been sent or uploaded to the Internet, this can be downloaded, transmitted and distributed by anyone, not just by its original author. As a consequence of this, the flow of diffusion cannot in any way be arrested. The victim may also experience the same aggression repeatedly and without the direct intervention of the perpetrators: access and execution of the harmful digital content it can be repeated by the victim. Internet is over the control of both perpetrators and victims. Evil contents remains on the Web indefinitely and consequences are unpredictable.

Bullies can take advantage of some features of online communication (anonymity, asynchrony and accessibility) to harass their victims continuously and automatically (Valkenburg & Peter, 2011).

The same notion of *power imbalance* can assume different and more complex connotations (Law, Shapka, Hymel, Olson & Waterhouse, 2012). For example, it has been argued that cyberbullies have a deep understanding of technology and take advantage of their anonymity. The reality may be quite different: cyberbullies could be less technologically skilled than their victims and use the technology only as an extension of their hurtful

actions, for example, to document aggressions and humiliations through smartphone videocameras. Many traditional acts of bullying, once filmed and posted on YouTube, become acts of cyberbullying. It has been observed that anonymity provides to victims of traditional bullying the opportunity to revenge themselves online, attacking in the virtual world who torment them in the real world (Kowalski et al., 2008). An online survey of 473 students (König, Gollwitzer & Steffgen, 2010) investigated the phenomenon of revenge and retaliation as a motive to engage in acts of cyberbullying and showed that 149 cyberbullies were victims of traditional bullying.

Notwithstanding the obvious individual differences, it seems that cyberbullies tend to choose their victims among their former persecutors.

In Table 2, the most common effects of acts of cyberbullying on their victims are synthesized, referring them to the emotional, behavioral, and cognitive spheres.

The more one studies cyberbullying, the more one realizes that this is a multifaceted and complex phenomenon.

In a very simple way, cyberbullying discloses two different faces, due to the different use of communications technology. Online bullying cannot simply be deemed as an extension of the traditional

bullying. To continue to claim that it is “new wine in old bottles” (McGuckin, Cummins & Lewis, 2010) leaves in the shadow important aspects of the phenomenon. If it is true that the victims of cyberbullying often know their persecutors and many dynamics which tie persecutors to victims are the same as in traditional bullying, cyberbullying shows something new. This concerns the nature of virtual relations and how they are perceived and managed today, especially by young people. Cyberbullying is evil and dangerous not only because it involves the sphere of intimacy of individuals and their reputation, but also because it undermines the communicative dimension. Stop to be connected to avoid harassment is tantamount, in particular for young people, to close their relationships with the world.

On this purpose, we have to consider that mostly of victims of cyberbullying are teenagers of 12-13 years. The research attributed this to several factors: the transition to the secondary school, a greater degree of autonomy from parents, the availability of smartphones, the growing interest to socialize, and so on. There is an element that should not be undervalued: young people are not likely to report their persecutors. They are afraid that adults will prevent them the use of the Internet and smartphones, and sometimes are even ashamed to show what circulates about them.

Table 2. Cyberbullying consequences

Type of Consequence	Appearance
Emotional	• Anxiety symptoms • Depressive states • Sense of shame • Sense of abandonment and despair • Various somatizations
Behavioral	• Exclusion, marginalization • Sleeping and eating disorders • Posture problems • Aggressive responses • Self-harm • Substance abuse
Cognitive	• Attention disturbs • Learning and speech difficulties • Confusion • Poor academic results

FUTURE RESEARCH DIRECTIONS

Cyberbullying is a complex phenomenon and can be affected by numerous contextual factors that involve not only the personality of perpetrators, victims, bystanders, educators, and parents, but also their cultural sphere: cultural attitudes may influence cyberbullying, or at least its perception around the social context (Boronenko, Menshikov & Marzano, 2013).

Future research should explore this context more deeply and investigate the links between cyberbullying episodes, public reactions, and policy adoptions.

Furthermore, cyberbullying is a topic that encompasses several investigation perspective and a common effort is needed to overcome the current limitations of general reviews and the absence of large empirical data and analysis.

On this regard, a new interesting research area concerns the changes in the sexual behavior, especially among young people, and the related use of smartphones. (Espelage, 2016).

In the next paragraphs we highlight some new interesting research issues tied to two alarming emerging problems.

Revenge Porn

A new phenomenon which is so-called revenge pornography or revenge porn is recently spreading. It involves a perpetrator – typically an ex-partner from a previous romantic relationship – uploading nude or semi-nude images/videos of a person online without the consent of the person appearing in the content.

It has been observed that, despite recent media attention on revenge porn, relatively few academic studies have focused on this issue, and those that do concentrate mainly on the legal aspects and legal theories related to revenge porn cases.

Homophobic Cyberbullying

Many sites of gay associations denounce the existence of a homophobic cyberbullying, and argue on the spread of this phenomenon. Finding of a survey conducted at British schools in 2012 by the *Centre for Family Research* of the Cambridge University are broadly diffused. This data is also reported on the major networks engaged combating cyberbullying.

Despite the seriousness and topicality of the problem, few studies are available on discriminatory aspects of cyberbullying, including racism and homophobia. Scientific investigations on homophobic cyberbullying are rather limited and data doesn't allow an effective assessment of this phenomenon. For example, in Canada, there are

studies that show conflicting data. According to a recent study, 29.4% of young gays are victims of homophobic cyberbullying (Cénat, Blais, Hébert, Lavoie & Guerrier, 2015); while a previous survey reported that the victims of homophobic cyberbullying are about 61% (Blais, Gervais, & Hébert, 2014).

At the moment, it is not well defined what homophobic cyberbullying means, and researchers have not developed common methodologies of analysis.

Certainly, investigating homophobic component within the complex area of cyberbullying could contribute to a deeper understanding of this phenomenon. However, emotional generalizations induced by gay activists and media exploitation of some extreme cases of online homophobic harassment don't facilitate the scientific analysis.

CONCLUSION

Many advices about preventing cyberbullying concern training children and their parents in e-safety and implementing technological tools to counteract the cyberbullies' behaviour, such as blocking bullying behaviour online or creating panic buttons for cyber victims that they can push when feeling under threat (Marzano, 2015).

However, designing preventive strategies is not simple at all: effective preventing programs need the knowledge of new media and the understanding of their use by the different typologies of users, especially by adolescents and young people.

There is a general consensus that prevention through education is the better strategy against cyberbullying. All researchers and educators concord with the opinion that criminalization is not the right answer to combating cyberbullying, since its negative consequences outweigh the possible positive effects. Internet safety education has proven effective, and empowering educators with theoretical and practical tools is an extremely valid key.

Peer education programs and peer support models are also deemed useful. They are based on the assumption that peers learn from one another, having significant influence on each other. Conducts and behaviours are most likely to change when liked and trusted group members take the lead in changing the situation (Naylor & Cowie 1999; Turner & Shepherd, 1999; Maticka-Tyndale & Barnett 2010).

There are several curriculum based programs available to educators that strive to help in preventing cyberbullying (Snakenborg, Van Acker & Gable, 2011). Some examples of cyberbullying combating programs are also available on the Internet, while prevention programs focus at school level appear to be more efficient (Couvillon & Ilieva, 2011).

However, in fighting cyberbullying, we need a continuous monitoring of both technologies and their use (see the recent anonymous social networks' spread).

KEY TERMS AND DEFINITIONS

Anonymous Social Media: Social media that ensure members anonymity.

Bullicide: Suicide due bullying.

Bystanders: Persons that make decision to stay out of cyberbullies aggression and don’t intervene.

Cyberspace: The online world of computer networks and the Internet.

Cyberspace Relative Anonymity: The relative possibility to perform activities on the Web without being identified.

Homophobia: Is the irrational fear or hatred of homosexuality.

Revenge Porn: Is the publication of sexual explicit material portraying someone who has not consented for the image or video to be shared.

Defining and Conceptualizing Cyberbullying

Karin Spenser

Nottingham Trent University, UK

Lucy R. Betts

Nottingham Trent University, UK

INTRODUCTION

The word ‘bully’ dates back to the 16th century and the original meaning is somewhat different to that of today. Originally a term of endearment implying friendly admiration but over time the meaning of bullying has darkened to “a person who uses strength or influence to harm or intimidate those who are weaker” (Oxford English Dictionary, 1989). Until recently face-to-face bullying was seen by some as a normal and acceptable part of youth (Koo, 2007). The practice, tolerated within England’s public school system for decades, appears in both fiction and real life. In *Tom Brown’s School Days*, the character Flashman is seen bullying the younger Tom Brown; the line “‘very well then, let’s roast him’ [...]. One or two boys hesitate, but the rest join in” (Hughes, 1857, p. 188), being the most famous. At a similar time, the death of a 12 year old boy attending the King’s School in Cambridge, was made public. The boy’s death, in 1885, was attributed to experiences of bullying. Afterwards, a former student wrote to the editor of *The Times* newspaper saying “bullying, of the kind mentioned, constantly occurred during the seven years I was at the school” (Anon, 1885).

The turning point, in recognizing face-to-face bullying as a problem, came in the 1970s. At that time, a general concern regarding violent behavior emerged and the pioneering work of Olewus (1978) began to address young people’s experiences of bullying. Since then numerous studies have examined various forms of face-to-face bullying

(e.g., Hawker & Boulton, 2000). However, in the wake of societal and technological changes bullying has evolved (Hinduja & Patchin, 2008). Recent statistics report that 99% of all 12- to 14-year-olds in the UK are frequent internet users with young people spending increasing amounts of time using technology (Office for National Statistics, 2013). With the many benefits of this connectivity, such as enhanced educational attainment (Jackson, 2011) and social networks (Valkenburg & Peter, 2007), there are also risks. Cyberbullying has been identified as one of the greatest risks (Cross, Monks, Campbell, Spears, & Slee, 2011). Cyberbullying is “the intentional act of online/digital intimidation, embarrassment, or harassment.” (Mark & Ratliffe, 2011, p. 92).

BACKGROUND

Although cyberbullying is undoubtedly a by-product of the union of adolescent aggression and electronic communication; it is its propensity for growth which gives cause for concern for researchers and educational practitioners (Cassidy, Faucher, & Jackson, 2013). Further, empirical evidence reports that the impacts of cyberbullying include: distress (Li, 2010), loneliness (Sahin, 2012), depression (Tynes, Rose, & Williams, 2010), increased psychosomatic symptoms (Sourander et al., 2010), suicidal ideation (Hinduja & Patchin, 2010), and reduced academic performance (Smith et al., 2008).

DOI: 10.4018/978-1-5225-2255-3.ch361

Despite this attention, many questions remain unanswered with regard to the conceptual and theoretical similarities between face-to-face bullying and cyberbullying. It is widely accepted that definitions of face-to-face bullying include aspects of repetition, power imbalance, and intention (Olweus, 2013). There are three forms of face-to-face bullying: physical, verbal, and social (Rigby, 1997). Physical bullying is a ‘direct’ form of aggression that involves hitting, punching, kicking, or any other action that can inflict physical pain or harm. The power imbalance between the perpetrator and the target in physical bullying makes it difficult for the target to defend themselves and prevent the actions being repeated (Rigby, 2002).

Verbal bullying which includes making rude remarks, telling hurtful jokes about an individual, calling an individual hurtful names, and threatening an individual with the intent to intimidate or humiliate the target, or to provide ‘humor’ at the expense of the target (Crick et al., 2001) can be direct or indirect. The perpetrator can ‘directly’ bully by teasing, taunting, or mocking the target to their face, or ‘indirectly’ bully by doing the same thing behind the target’s back (Cole, Cornell, & Sheras, 2006).

Social bullying is aggressive behavior in the form of rumor spreading, backbiting, and social exclusion that results in harming an individual’s psychological state of mind and/or social connections. Often delivered in a covert manner social bullying allows the perpetrator to remain anonymous (Björkqvist, Österman, & Kaukiainen, 1992).

Issues, Controversies, Problems

The reported prevalence rates of cyberbullying vary from 6.5% (Jones, Mitchell, & Finkelhor, 2012) to 72% (Juvonen & Gross, 2008) with frequencies converging between 20 to 40% (Hinduja & Patchin, 2008). Typically, cyberbullying experiences peak around the age of 14 (Ortega et al., 2009), although those most at risk of being involved

in cyberbullying are adolescents and young adults (Ševčíková & Šmahel, 2009). Tokunaga (2010) proposed that a holistic view of cyberbullying should be adopted to include: aggression, hostile, and harmful acts via an electronic device. Clearly, not all acts encountered online may be intended or interpreted as cyberbullying; young people make the distinction between cyberbullying behaviors and banter (Spenser & Betts, 2014). Banter is an “interactional bonding game” (Dyrel, 2008, p. 246) that is interpreted as playful by participating individuals rather than having sinister undertones.

Willard (2007) suggested eight forms of cyberbullying: Flaming (angry and vulgar online messages); harassment (repeated sending of nasty and insulting messages to the victim); denigration (spreading of rumors and gossiping about a person online to damage his/her reputation or friendship); impersonation (causing someone to get into trouble or damaging someone’s reputation by pretending to be that person); outing (sharing secrets or humiliating information); trickery (convincing someone to share humiliating information, then making it available); exclusion (intentionally excluding someone from an online group in order to cause hurt); and cyber stalking (repeatedly harassing someone such that the person feels threatened or afraid). There are a number of high profile cases where the types of cyberbullying identified by Willard have been attributed as a contributing factor to young people’s suicide. For example, Ryan Halligan committed suicide after being duped by an individual who befriended him, humiliated him, and then sent threats via instant messenger which were subsequently circulated to the wider peer group (Moreno, 2011). Clearly parallels exist between face-to-face bullying and cyberbullying; however, cyberbullying has some unique characteristics. The chapter will now discuss seven facets of cyberbullying that are particularly pertinent to the definition and conceptualization of cyberbullying: anonymity, access, repetition, permanency, publicity, power, and identity and motivation.

Anonymity

Physical and verbal face-to-face bullying identify the perpetrator to the target. In contrast, cyberbullying allows the perpetrator to hide their identity through creating: anonymous screen names and web pages, false identities, and unidentified numbers. Indeed, Kowalski and Witte (2006) found that 74% of targets of cyberbullying did not know the identity of their attacker. More recently Spenser and Betts (2014) reported participants believed anonymity may actually empower and encourage individuals to engage in cyberbullying. Anonymity can have a disinhibiting effect on the perpetrator of cyberbullying, leading individuals who might not otherwise engage in face-to-face bullying behaviors to do so more comfortably online (Vandebosch & van Cleemput, 2009). In other words the lack of immediate consequences combined with the inability to see the targets' emotional reactions often means that self-regulatory processes, employed during face-to-face contact, are disregarded (Kowalski, 2009). From the point of view of the target, being unaware who is causing the harm can be very daunting and can cause negative emotions such as frustration, insecurity, and fear (Dooley, Pyzalski, & Cross, 2009). Consequently, future research should explore the role and effect of anonymity and the extent to which targets of cyberbullying know the identity of their perpetrator.

Access

For the most part, face-to-face bullying takes place at school; thus giving the target a chance to retreat to a 'safe' place after school hours. Conversely, cyberbullying can occur anywhere and at any time. Through technology, the cyberbully is able to extend their bullying beyond the school grounds and 'follow' their target home. Consequently, the target is potentially accessible 24 hours a day. Recent research by Betts and Spenser (2015) reports that teachers perceive the fear of receiving

a message at any time to have a greater impact on young people who are the target of cyberbullying than the content of the message. The only way to avoid these messages is for the target to 'dispose' of their electronic devices. However, this does not stop the perpetrator from posting messages for the online community to see (Kowalski, 2009). Further, young people are unlikely to give up their electronic devices because of the fear of missing out. Fear of missing out is characterized by the desire to remain continually connected to social media (Przybylski, Murayama, DeHann, & Gladwell, 2013). This fear is motivated by the belief that others are having 'rewarding experiences' that the individual is not part of and is exacerbated through social media when individuals learn that others have had such experiences. Therefore, when exploring cyberbullying researchers must ensure that young people's reports do not subsequently impact on their access to technology as a way to try to overcome the under-reporting of cyberbullying.

Repetition

Olweus (1993) argued that, as face-to-face bullying behaviors take many forms, it is the repetitive nature of the act that is crucial rather than the behavior *per se*. Repetition in face-to-face bullying serves to instill fear and cause psychological harm to a target although in cyberbullying it is more difficult to operationalize. Whilst repetition is clear when a perpetrator posts numerous messages (Slonje & Smith, 2008), it is not so clear when a perpetrator creates a single derogatory comment, which is then repeatedly accessed resulting in widespread ridicule and humiliation. Further, not all forms of cyberbullying are equal in terms of impact on the target (Smith et al., 2008). For example, receiving an offensive text message is not the same as someone posting an embarrassing or humiliating photograph or video of the target online. Therefore, it follows that some acts may not need to be repeated (or repeated as often) to induce the same or greater harm (Slonje & Smith,

2008) and, as such the frequency of repetition should be controlled for in future studies assessing cyberbullying.

Permanency

Whilst undoubtedly unpleasant, once performed the act of face-to-face bullying is over. People may have witnessed the act of face-to-face bullying and they may talk about it for a while, but it is likely to then be forgotten. However, with cyberbullying the act potentially never goes away. When internet users visit various web sites, they leave behind evidence of which sites they have visited. This collective, ongoing record of one's web activity is called the 'digital footprint' (Greysen, Kind, & Chretien, 2010). Often young people, who lack an awareness regarding privacy issues and post inappropriate messages, pictures, and videos, do not fully appreciate the fact that 'what goes online stays online' (Palfrey, Gasser, & Boyd, 2010). As a result a young person's future may be put into jeopardy by inexperienced and rash 'clicks of the mouse' (O'Keeffe & Clarke-Pearson, 2011). Consequently, longitudinal studies are required to determine the psychosocial effects of the relative permanency of cyberbullying episodes.

Publicity

It has been noted that one of the most distressing aspects of face-to-face bullying is the effect of the group (Crick, Grotpeter, & Bigbee, 2002). This aspect of face-to-face bullying may have similarities with cyberbullying in that when cyberbullying episodes are public the impact of the behaviour is likely to be more serious. However, the audience for cyberbullying is potentially limitless (Nocentini et al., 2010).

Aligned to the public nature of cyberbullying is the controllability of the situation. The ability to control what is posted on line by others is completely beyond the targets' reach. This lack of control is associated with feelings of helplessness, helpless reactions, and helpless coping strategies

(Spears, Slee, Owens, & Johnson, 2009), which are in turn associated with depressive symptoms (Machmutow, Perren, Sticca, & Alsaker, 2012). Consequently, the size and scope of the audience who witness cyberbullying episodes should be assessed by researchers to gain insight in to the impact of publicity.

Power

Power imbalance is a fundamental aspect of bullying with Olweus (1978) making reference to the 'weak' target who is both physically and psychologically weak. Power can be social, psychological, or physical in nature (Monks & Smith, 2006). However, assessing the power imbalance in cyber-based interactions is more complicated. One study undertaken by Vandebosch and van Cleemput (2008) with 10- to 18- year-olds found that those individuals who were considered to be more powerful in face-to-face interactions were sometimes targeted online due to the anonymity that technology affords. Consistent with this empirical evidence, Fauman (2008) suggested that the ability to remain anonymous may minimize the necessity for those that engage in cyberbullying to be more powerful than their targets. In addition, whilst the perpetrator of cyberbullying may be perceived as being more technically advanced than their target, in reality it does not require an advanced ability to take a picture using a mobile phone camera and send it to others. Similarly, posting a picture online or creating a fake social network site profile requires little skill (Smith et al., 2008). Therefore, when assessing cyberbullying, it is important to consider the real or imagined power dynamic between the perpetrator and target.

Identity and Motivation

As with most competitive situations, the social struggle amongst young people has a hierarchy. Face-to-face bullying is a component of this hierarchy. According to Olweus (2001), there are seven different levels within the bullying ladder:

those who want to bully and initiate the action, their followers or henchmen, supporters or passive bullies, passive supporters or possible bullies, disengaged onlookers, possible defenders, and defenders who dislike the action of bullying and help those that are target. However, the identity of the perpetrator of cyberbullying is less straight forward.

Aftab (2011) suggests that perpetrators of cyberbullying fall into five different groups. The ‘vengeful angels’ see themselves as righting wrongs or protecting themselves or others. The ‘power-hungry’ want to exert their authority and show that they can make others do what they want them to do such that they will continue to escalate their actions until they get a response. This group of cyberbullying perpetrators most closely resembles the perpetrators of face-to-face bullying. The ‘nerd’ targets individuals directly, keep their activities secret, and rarely appreciate the consequences of their actions. The ‘accidental cyber bully’ does not recognize that they are a perpetrator of cyberbullying and they do not lash out intentionally. ‘Mean girls’ are girls who engage in cyberbullying, have high social status and tend to target individuals to overcome boredom with the aim of damaging the targets’ social status. In addition to these groups, there is also evidence that perpetrators of cyberbullying have previously been the target of face-to-face bullying (Steffgen & König, 2009). Therefore, when examining cyberbullying researchers should examine the motives of those who act as perpetrators.

SOLUTIONS AND RECOMMENDATIONS

The characteristics of cyberbullying discussed so far in this chapter have implications for how cyberbullying is defined and operationalized to enable accurate and reliable data to be collected. Specifically, although anonymity, power, motivation, permanence of messages, access, and

publicity are recognized as distinct features of cyberbullying, one of the biggest challenges is how to capture these facets in tools designed to assess cyberbullying.

A recent review by Kowalski, Giumetti, Schroeder, and Lattanner (2014), argued that the definitions of cyberbullying comprised four distinct components: “(a) intentional aggressive behavior that is (b) carried out repeatedly, (c) occurs between a perpetrator and victim who are unequal in power, and (d) occurs through electronic technologies” (p. 1073). However, whilst these components relate to the facets of cyberbullying discussed in this chapter, it is not clear how these are captured in measures designed to assess cyberbullying. Therefore, the first recommendation is to present participants with these aspects of cyberbullying and ensure that they are all fully assessed in scales. Alternatively researchers could consider providing participants with a definition of cyberbullying or generating a ‘user’ defined conceptualization of cyberbullying. A final solution would be to ask participants to estimate the frequency with which they have experienced, or engaged in, a particular behavior to determine the repetition element of the definition. Participants could also be asked to report the perceived power dynamics and intention in the episode of cyberbullying. Developing appropriate strategies to assess cyberbullying will also enable researchers and practitioners to gain a clearer understanding of the prevalence rates of cyberbullying.

A second recommendation that arises from the literature discussed in this chapter relates to how cyberbullying can be distinguished from face-to-face bullying. In particular, it is important that when researchers design studies to assess cyberbullying that assessment tools distinguish between aspects of face-to-face experiences and cyberbullying. Researchers should also be mindful that young people may under-report their experiences of cyberbullying because of concerns associated with restricting access to technology. Together these recommendations will enable a more realistic appraisal of cyberbullying.

FUTURE RESEARCH DIRECTIONS

As alluded to in the section on solutions and recommendations, future research should consider how young people conceptualize cyberbullying. Taking a young person centered approach to the definition of cyberbullying, similar to Spenser and Betts (2014), will allow greater exploration in to how young people conceptualize behavior as cyberbullying and what the distinguishing features between cyberbullying and ‘banter’ are. Similarly, exploring teachers’, educational practitioners’, and parents’ understanding and conceptualization of cyberbullying similar to the work of Betts and Spenser (2015) will add to understanding in this area from alternative perspectives. Further, by gaining a greater appreciation of how young people and key stakeholders conceptualize cyberbullying this may go some way to address the current debate in the literature with regard to repetition, the power imbalance, and intention associated with cyberbullying.

In addition to developing and refining tools to assess cyberbullying, future research should also examine the extent to which the distinct facets of cyberbullying discussed in this chapter impact on young people’s psychosocial adjustment. Whilst there is growing evidence of the impact of cyberbullying on adjustment (e.g., Hinduja & Patchin, 2010) it may be that the different facets of cyberbullying have influence adjustment through different mechanisms. Therefore, future research should further explore this area.

CONCLUSION

In summary, cyberbullying differs from face-to-face bullying in a number of ways. Whilst these are not absolute differences they may affect other aspects such as motives for perpetration and impact on targets. Although there is some consensus in the

academic and practitioner literature that cyberbullying comprises a set of aggressive behaviors that are enacted via electronic media, relatively little is known about some aspects of cyberbullying. For example, there is limited research examining the motivations and goals of those who engage in cyberbullying and the long-term impact of experiencing cyberbullying either as a perpetrator or as a target. This in turn makes it difficult to develop interventions to address this behavior. With the increasing availability, use and reliance on electronic technology, the issues outlined here are going to become progressively more important and are clearly worthy of far greater understanding. There is a clear need for further in-depth research addressing issues of anonymity, access, repetition, permanency, publicity, power, identity, and motivation.

KEY TERMS AND DEFINITIONS

Cyberbullying: An aggressive act or behavior targeted towards an individual via digital technology.

Digital Footprint: The record of activity that an individual leaves when using technology (often without their knowledge).

Face-To-Face Bullying: An aggressive act or behavior targeted towards an individual in the same physical environment.

Fear of Missing Out: The belief that others are having 'rewarding experiences' that the individual is not aware of.

Perpetrator: The person who engages in an act of face-to-face bullying or cyberbullying.

Social Disinhibition: The reduction in awareness of social conventions and normative behaviors.

Target: The person who an act of face-to-face bullying or cyberbullying is directed towards.

Developing Creativity and Learning Design by Information and Communication Technology (ICT) in Developing Contexts

Chunfang Zhou

Aalborg University, Denmark

Aparna Purushothaman

Aalborg University, Denmark

INTRODUCTION

This chapter has two aims: (1) to establish the link between creativity, learning, information ecology and community of practice that underpins the theoretical necessity of a contextual user-centered approach to learning design for ICT in developing contexts; and (2) to specifically discuss how a Human Computer Interaction for Development (HCI4D), based on learning design, can be applied to provide the practical instrument for building creative learning environments in developing contexts. Accordingly, the chapter will develop a new theoretical framework by using three prominent theories: creativity theory, information ecology, and the theory of communities of practice. This chapter also offers practical contributions to developmental scholars and project managers in the form of a vocabulary to address the process and learning issues in both formal and informal learning environments, and by opening up new ways of understanding creativity, learning and usages of ICT in a developing context.

BACKGROUND

Generally, the term creativity means to develop new and useful ideas (Amabile, 1996). The development of different perspectives in describing creativity has been traced from the focus of the 1950s to the 1970s on areas of personality, cogni-

tion and the stimulation of creative individuals, to the awareness in the 1980s and 1990s of the influence of environments and social contexts on the creativity of individuals, groups and organizations (Loveless, 2007). In addition to discussion of the characteristics of novelty, effectiveness and ethicality (Cropley, 2001), the current creativity discourse also encompasses (1) operating in the economic and political field, (2) acting as a possible vehicle for individual empowerment in institutions and organizations, and (3) its use in developing effective learning (Jeffrey & Craft, 2001). Creativity is, therefore, now discussed as “a good thing”, promoting both personal expression and enhancing opportunities to engage in the complexities of problem-solving in the economic and cultural landscape of the 21st century (Loveless, 2007).

The uses of information communication technology (ICT) to support creativity by learning design have been described, reviewed and theorized in a range of published work in recent years (Loveless et al., 2006). ICT can be seen as a set of tools, which can be chosen as and when they are appropriate to creative processes. It can be argued that the characteristics of ICT can also make a distinctive contribution to those processes, providing new tools, media and environments for learning to be creative and for learning through being creative (Loveless, 2007). In particular, the use-centered approach to learning design by ICT can be viewed as a potential strategy to promote

DOI: 10.4018/978-1-5225-2255-3.ch362

learners' creative thinking skills and to improve learning abilities (Purushothaman, 2013). As explored by the domestication theory, the arrival of ICT in homes has brought with it the mobilization of material resources, skills, cultural values and social competences and capabilities. The recent rise of social media is also having an influential impact on organization innovation. These applications have shifted the way that users seek information and create and connect knowledge (Loveless, 2007). In developing contexts, designing learning for creativity by ICT should be paid more attention than in developed contexts due to the complex technical, economic, social and cultural problems.

DEVELOPING CREATIVITY AND LEARNING DESIGN IN DEVELOPING CONTEXTS

Designing Creativity-Based Learning Environment by ICT

In the 21st century, we are moving towards the “creative society”. In so doing, success in the future - for individuals, for communities, for companies, for nations as a whole — will be based not on what we know or how much we know, but on our ability to think and act creatively. Meanwhile, the rapid development of technology, mainly as a result of the internet, such as ICT, has brought about an upsurge of technological tools which young people are appropriating in their everyday lives (Purushothaman & Zhou, 2014).

Wheeler, Waite, and Bromfield (2002) propose a model for the creative use of ICT in learning which includes dimensions of problem-solving, creative cognition and social interaction. The model shows that the three dimensions are independent but interactive and, in some cases, it may be difficult to distinguish between them. This means that creativity development would need to incorporate social interaction within the community of activity. Furthermore, according to

Loveless et al., (2006), the framework for creativity and ICT attempts to describe the interaction between three elements of creative practices with ICT: creative processes (for example, using imagination, fashioning, pursuing purpose and evaluating originality and value), the features of ICT (for example, provisionality, interactivity, capacity, range, speed, automatic functions and multimodality), and ICT capability as an expression of elements of higher order thinking-finding things out, developing ideas and making things happen, exchanging and sharing information and reviewing, modifying and evaluating work as it progresses through a breadth of study. Thus, it is important to note that it is not the access to digital resources, which “delivers” creativity, but the opportunities such access affords for interaction, participation, and the active demonstration of imagination, production, purpose, originality and value (Loveless, 2007).

Needs of Learning Design by ICT in Developing Contexts

Designing for learning to use a technology in a developing world scenario is often constrained because of complexity and the impact of socio-cultural factors that influence ICT usage. These factors include patriarchal gender roles, illiteracy, cultural beliefs and values. This chapter takes the position that in order for the successful acceptance and usage of technology in a developing context, greater focus has to be placed on the design elements of the technological usage in the context where it will be used. This is very important because, in most cases, the design dimensions that are successful in the western world are adapted without sufficient consideration of the social and local contextual factors in a developing scenario where they are then introduced and used. As development is a social phenomenon and ICT is a technical phenomenon, ICT design framed for developmental goals should analyze the intervention strategies based on socio-technical terms (Dearden & Rizvi, 2009). The technological

design elements of developed countries may not fit into the culture of developing countries (Dray, Siegel, & Kotzé, 2003), thus, more effort should be made in developing contexts.

THEORETICAL UNDERPINNINGS

A Sociocultural Perspective to Learning and Creativity

This chapter takes a socio-cultural perspective on learning and creativity. Socio-cultural approaches to the study of learning represent a move away from the decontextualized, individualistic approach of certain types of cognitive psychology towards more collective, social and participatory types of framing (Haggis, 2008). In this regard, we can say that learning is always learning-in-context; a further element is learners' engagement, through which learning happens. Furthermore, in the social learning system, new patterns can be acquired through direct experience or by observing the behaviors of others. The more rudimentary form of learning, rooted in direct experience, is largely governed by the rewarding and punishing consequences that follow any given action. People are repeatedly confronted with situations with which they must deal in one way or another. In other words, during the course of learning, people not only perform responses, they also observe the differential consequences that accompany their various actions. On the basis of this informative feedback they develop thoughts or hypotheses about the types of behavior most likely to succeed. These hypotheses then serve as guides for future actions (Bandura, 1971).

As noted, creativity can be regarded as a driver for learning process. Socio-cultural theory posits that creativity can be described as an interaction between characteristics in people and communities, creative processes, subject domains and the wider social and cultural context (Loveless et al., 2006). Csikszentmihalyi (1996) proposes that creativity arises from the interaction between the

“intelligence” of individuals, the domain or areas of human endeavor, disciplines, crafts or pursuits and the field, such as people, institutions, reward mechanisms and “knowledgeable others” through which the judgements of individual performances in society are made. The levels of achievement of originality for individuals, peer groups or within the domain, are evaluated within the field, whereas the judgement of value can relate to the individual's critical reflection as well as recognition of a unique contribution to the domain itself. Creativity can, therefore, be seen in the interaction between a person's thoughts and actions both as an individual and in communities, their knowledge and skills within a domain, and within mediating cultural tools, and a socio-cultural context which can encourage, evaluate and reward. This has important implications for thinking about creativity where the learning environment might either nurture or dismiss the development of creative individuals, groups and communities (Loveless et al., 2006).

Information Ecology and Communities of Practice (CoP): Theoretical Roots for Designing for Learning by ICT

Information ecology is a “system of people, practices, values and technologies in a particular local environment” (Nardi & O'Day, 1999, p. 49). “An information ecology deals with the local differences while still capturing the interrelationships among the social, economic and political context in which the technology is invented and used” (Nardi & O'Day, 1999, p. 47). According to this theory there is an element of uncertainty that the adoption of new technologies brings to the quality of life and work. It asserts that “people often distance themselves from a critical evaluation of technologies in their lives, as if these technologies were inevitable forces of nature rather than things we design and choose” (Nardi & O'Day, 1999, p. 14). The theoretical underpinning of “value and beliefs” can help with the understanding of how the intended value of the technology and the

beliefs of the users impact on the specific ICT. The “why” aspect of the theory will help us to understand why the specific ICT is needed for the target group.

To address the socio-cultural aspect of learning to use the technology in a developing context, the design uses Wenger’s (1998) social theory of Communities of Practice (CoP). CoP has its roots in the situated theory of learning, which is an alternative approach to the dominant cognitive perspectives on learning. “Communities of practice are formed by people who engage in a process of collective learning in a shared domain of human endeavor: a tribe learning to survive, a band of artists seeking new forms of expression, a group of engineers working on similar problems, a clique of pupils defining their identity in the school, a network of surgeons exploring novel techniques, a gathering of first-time managers helping each other cope ” (Wenger, 2006, p. 1). In CoP, learning is seen as a form of social participation. “Participation here refers not just to local events of engagement in certain activities with certain people, but to a more encompassing process of being active participants in the practices of social communities and constructing identities in relation to these communities” (Wenger, 1998, p. 4). Thus, learning is not just the accumulation of skills and information, but also a process of becoming.

A LEARNING DESIGN BY ICT: HUMAN COMPUTER INTERACTION FOR DEVELOPMENT (HCI4D)

What is HCI4D?

Human Computer Interaction for Development (HCI4D) focuses on the “relationship between humans and technology in the context of international development, ranging from lower-level interface design issues to higher-level social interactions” (Anokwa et al., 2009). The socio-cultural aspects

that influence the design and usage of technologies in developing countries are at the core of HCI4D (Winters & Toyama, 2009). This addresses questions of “how interactive products, applications, and systems can be appropriately designed to both address the distinctive needs of users in developing regions, and to cope with the difficult infrastructural contexts where these technologies must work” (Ho, Smyth, Kam, & Dearden, 2009, p. 1). Thus, fundamentally, HCI4D deals with designing ICT tools and technology that can be used by marginalized people to better their lives.

This chapter proposes a design that is driven by the social learning aspect of the efficient use of technology, an aspect that is rarely addressed in the HCI4D literature. Most of the HCI4D designs place emphasis on the product outcomes. There is a desperate need from the scholars that the digital divide can be discussed by addressing the issues that are central to HCI4D, such as how to improve the fit between technology, human needs and human context and how to design technology to facilitate human interaction with the technology (Dray et al., 2003). The focus on learning is mainly driven by the fact that “in the learning approach, outcomes come through the ongoing process of using ICT’s rather than from the product of ICT’s and process can be explicitly designed or shaped through understanding informal learning which links between actions and use and informal learning outcomes” (Foster, 2011, p. 2).

By taking HCI4D as an example, we propose a design for learning to use ICT that has design components that the scholars and designers can consider for the efficient acceptance and usage of ICT in a developing context. The design takes contextual factors as its backbone. The design also takes into consideration the theoretical underpinning of information ecologies, as proposed by Nardi & O’Day (1999), which can assist designers of ICT in a developing context to understand how people value the specific ICT, what perceptions they hold about ICT, and why the specific ICT is going to be useful for the intended users in a

developing context. A further design dimension that is an important aspect when seen from a digital divide perspective, is that the design should provide opportunities for identity work and should focus on the social and cultural practices of the context in which learning takes place. The design takes into consideration the socio-cultural learning theory developed by Wenger (1998) which will enable designers and scholars to design according to how the participants experience ICT usage and how they understand and perceive themselves as ICT users. This can be achieved by providing them with the scope to construct identities as ICT users which can, in turn, make learning to use ICT more effective for the participants. The learning design also incorporates appropriate training programs for the users of technology for the long-term sustainability of developmental efforts.

Contextual Factors

The first and most significant element when designing learning for any form of ICT in an HCI4D context is a thorough understanding of the contextual factors in which the ICT is to be used. “Sociocultural factors influence the perceived benefits of acquiring technology-related skills and availability of skills required to use a technology influences perceived ease of use and perceived usefulness of the technology and hence attitude towards its adoption” (Dholakia, Dholakia, & Kshetri, 2003, p. 14). Scholars note the significance of knowledge about the contextual design factors at the local level, such as sociocultural factors, technological factors, economic factors and users’ past ICT experiences, all of which are relevant for designing ICT in a developmental scenario (Parmar, 2009; Walton & Heeks, 2011; Winters & Toyama, 2009). We would emphasize that the specific background information of the intended users and the socio-cultural environment of the context where the ICT will be used should be thoroughly investigated.

Value and Beliefs About the ICT

How the intended users value the specific ICT that is introduced and what their beliefs are about the specific ICT are highly significant for acceptance and successful usage. Dearden & Rizvi (2009) state that whilst designing for ICT4D it is also important to examine what ICT might mean for the users in the context. “Values represent a manifestation of culture that signify espoused beliefs identifying what is important to a particular cultural group” (Leidner & Kayworth, 2006, p. 359). Studies show that cultural perceptions of technology influence the acceptance and future usage behavior of the users (Chen, Mashhadi, Ang, & Harkrider, 1999; Leidner & Kayworth, 2006). However, it is noted that there is a lack of attention to cultural beliefs and their impact on ICT adoption in developing countries (Albirini, 2006; Loch, Straub, & Kamel, 2003). Poor understanding of ideas, beliefs and values about how technology should be utilized in developing countries challenges the designers of technically advanced societies for successful implementation and usage of technologies (Straub, Loch, & Hill, 2001).

Values and beliefs about technology are the outcome of the socio-cultural structures that people belong to. Thus, cultural perceptions about the specific technology will significantly influence how they value and use the technology. People’s perceptions of ICT differ from culture to culture and the way in which they value ICT usage will also differ. If the intended users of technology are women, sufficient attention has to be given to the gender specific usage of the technology, how women value it, and what beliefs they have about the technology. Gendered roles are determined by cultural, social and economic factors and they differ within cultures and between countries (Moghaddam, 2010). These gendered roles, defined by cultural influences, impact on the usage of technology by women (Johnson, 2010; Primo, 2003; Purushothaman, 2013).

The concept of information ecologies developed by Nardi & O'Day (1999) can, in a developing context, provide insights for designers of ICT about how people value ICT and what perceptions they hold about the specific ICT that is introduced; thus, learning can bring effective results. The values and beliefs that participants hold about ICT have to be taken into consideration before the project begins and before they start to learn how to use the ICT. This is because if participants have negative attitudes and do not assign much value to ICT, before the training starts and they start to learn how to use the ICT, they have to be given a greater awareness of the potential benefits of the specific ICT and the positive changes it can bring to their lives. If participants do not believe in the technology and do not believe that using ICT can bring any value to their lives, making them learn how to use the technology and facilitating training and the scope for interaction and mutual engagement, and providing scope for constructing identities as ICT users (which is another design dimension addressed by this paper) may not be effective unless their negative beliefs about using the technology are changed.

Why the Specific Technology

A further important element that should be considered in the design is how the specific technology is going to add usefulness to the lives of the intended users. Nardi & O'Day (1999) state that the "technology that is in question should be evaluated to know what significance it holds and what it means for the users in settings" (p.69). There is usually a tendency to only consider the "how" question that deals with the practicality of technology, whereas "the 'know-how' questions do inform the design but it is equally important to ask the 'know-why' questions so that technology can be used productively" (Nardi & O'Day, 1999, p. 71). In an ICT4D context, consideration should be given to the possible ways in which they are going to use the specific ICT and how it can bring significance to their lives. This "why" question

can provide insight into the motivation for using a particular technology/tool, why the particular technology is best for the task at hand, why it fits well with the practices of the participants, and also, possibly, why it might not be fit for purpose.

Constructing Identity

The learning design should also provide the scope for constructing identities as ICT users. Since the design intervention in ICT4D is always situated (Dearden & Rizvi, 2009), and in CoP learning is viewed as negotiating new identities that are both situated and dynamic, a CoP-based learning framework can bring new ways of understanding learning and using any form of technological tool for development that is context situated and specific. Learning to use technology can be more effective when learning is conceptualized as a process of identity change rather than a process of gaining and transferring information through technology (Brosnan & Burgess, 2003; Mayes & Fowler, 2006). CoP can help in understanding how the users negotiate meaning, how they interpret the experiences of ICT usage and how they understand and see themselves as ICT users in this specific socio-cultural context.

Reducing Digital Divide and Training Programs

In developing ICT-based creative learning designs in developing contexts, challenges exist both in technology and in the social sciences. For example, reducing the digital divide requires improvements across all the dimensions of ICT (dubbed the 4C framework): computing, connectivity, content, and human capacity (Wang & Zhou, 2013):

- **Computing:** PCs are prohibitively expensive for most people, and shared access (e.g., community centers or cybercafés) becomes inevitable. PCs today are very difficult to use and even "experts" spend a lot of time maintaining their machines,

worrying about updates, security, compatibility of hardware, etc. As a complementary technology, non-PC devices are an important option, e.g., mobile phones.

- **Connectivity:** Whilst mobile technology is improving worldwide, it remains expensive, limited in rural areas, and poor at proving data connectivity.
- **Content:** Meaningful content is lacking in many languages and most content is not locally relevant. Today's systems tend to make people passive consumers of information instead of enabling the generation of local information. In addition, rich content demands multimedia (useful to overcome literacy issues), which, in turn, requires broadband connectivity.
- **(Human) Capacity:** Users need to be aware, literate, and innovative in order to harness the power of ICT. They should also be empowered to use ICT, both by society and by the state.

Meanwhile, training to use the specific ICT is very important for successful usage. Appropriate training programs should, thus, be an integral part of the learning design. The program should also be helpful for dealing with diverse issues in relation to creativity and learning in developing contexts. For example, in some areas women are not safe when they are alone and in public places at night (Wangmo, Violina, & Haque, 2004). This restricted mobility is a barrier to women's use of ICT in developing countries (Purushothaman, 2013). Therefore, if the intended users are women, the training programs need to be gender sensitive (Purushothaman, 2013).

FUTURE RESEARCH DIRECTIONS

As mentioned earlier, ICT usage does not occur in a vacuum but, rather, it occurs within social and cultural norms that also shape the digital divide between developed and developing con-

texts. ICT usage is based on policy and business models, especially regulation. Thus, in the long term, research on ICT must provide value and be sustainable from both a user and a provider perspective. Designers and developers of ICT should consider innovative ways to work with and develop understandings of the nature of digital technologies as a medium in creative process (Tongia, Subrahmanian, & Arunachalam, 2005). A creativity framework should underpin planning, practice and evaluation. The framework should recognize the interaction between individuals and communities, processes, domains and fields, and the characteristics of imagination, fashioning, pursuing purpose, originality and value judgments (Loveless, 2007). These elements stand as the core philosophy of user-centered approaches to learning design, for example, HCI4D, which offer great potential for bringing benefits to future development.

CONCLUSION

In developing contexts, learners should have opportunities to develop ICT skills and techniques in an authentic and challenging creative society. The information ecology approach, recommended in learning design, can bring new dimensions to the field of ICT4D by connecting the needs of participants in terms of skills for using ICT and in designing an intervention to match needs with the value that intended participants give to the ICT in question and what beliefs they have about the technology that is going to be introduced. CoP theory can offer developmental scholars and project managers a vocabulary for addressing the process and learning issues in informal learning environments and can open up new ways for them to understand how learning to use ICT based tools in a developmental context may occur. In short, this chapter offers both theoretical and practical contributions to areas such as creativity learning and to the future improvement of developmental efforts.

KEY TERMS AND DEFINITIONS

Creativity: Etymologically speaking, the term “creativity” means to generate new and useful ideas. The field of creativity was practically started from psychological studies. Today the field has seen an explosion of interest: creativity has been discussed much by the theories such as psychology, social psychology, cultural psychology, social culture and even philosophy.

Learning: Learning is the act of gaining new knowledge, behaviors, skills, or ability. It may be regarded as a process, rather than a collection of factual and procedural knowledge. Human learning may occur as part of education, professional development, or training.

Learning Design: It means to design a learning environment that is based on theories of learning and aims to facilitate learning process and improve learning quality.

Information Communication Technology (ICT): ICT are a set of tools those include computer, Internet, mobile phones and diverse communication devices that contributes to education system and social learning system.

Information Ecology: It is a theory that deals with the local differences while still capturing the interrelationships among the social, economic and political context in which the information technology is invented and used.

Human Computer Interaction for Development (HCI4D): It is a learning model that focuses on the relationship between humans and information technology in the context of international development, ranging from lower-level interface design issues to higher-level social interactions.

Communities of Practice: It is a theory rooted in the situated theory of learning that are formed by people who engage in a process of collective learning in a shared domain of human endeavor. In a community of practice, learning is seen as a form of social participation. Participation refers not just to local events of engagement in certain activities with certain people, but to a more encompassing process of being active participants in the practices of social communities and constructing identities in relation to the communities.

Existential Aspects of the Development E-Culture

Liudmila Vladimirovna Baeva
Astrakhan State University, Russia

INTRODUCTION

The e-culture first was mentioned at the end of the 1990s. According to the European tradition, e-culture was originally understood as a form of cultural heritage preservation and the opposition to the e-commerce. Later, the term was used for the notion of different objects having an electronic or other digital form. Nowadays, the “e-culture” is an interdisciplinary concept having connotations in Philosophy, Cultural Studies, Sociology, Political Science, Economics and of course in the field of information technologies.

In general, *E-culture* represents cumulative results of creative activity and communication of people under the conditions of the information technology implementation, which characterized with creating of free information space, a virtual form of expression, distant technology and content liberality.

Advanced high technologies represent a vector of the civilization development, mediating economic and communicative processes of the world formation. Under these conditions, the crisis of socio-cultural and individual identity escalates, “technogenic” values extrapolate on the sphere of the interpersonal interaction. The ideologeme of technocentrism devaluates the traditional axiological models, informative and technogenic directivity of social and anthropological dynamics and determines new types of interaction both on structural and spiritual levels of social being. Under the domination of new technogenic institutes, the dysfunction of cultural and spiritual regulators of the social development occurs, in particular, the traditional ethical and epistemologi-

cal mechanisms of the public conscience shifting to massive, irrational and virtual sphere are broken. The sphere of the social discourse, mediated by electronic mass media, separates from subjects, making human beings feel the quasi reality being, solitude and desolation in the “boundless” information space.

The peculiarity of the present day age became the situation of the uncontrolled technological development, that is unique in its own way and requires detailed study, as its consequences have already caused significant deformation of psychology, world view, values and society. One of the most striking phenomena of the digital age becomes the formation of new digital culture (e-culture). Although, the concept “e-culture” has been still developing, it is evident it cannot be compared as a phenomenon with anything that has ever existed what requires the necessity of its detailed study.

Methodological basis of the research is related to the set of categories and the principles of existential philosophy and philosophical anthropology. The theories by M.Heidegger, V.Frankl and N.Abbagnano, A. Meneghetti have influenced on the formation of the conception of existential axiology in different ways. The research of the structure and the essence of values by R. Hartman, R. Frondizi, S.O. Hansson, symbolic and logical expression of a value by G.Vernon, the correlation of meaning and significance of a value structure, the search for subject and object of values by K.Baier, the ethical content of values by R.Brumbaugh, vital and existential analysis of values - A. Maslow, Ph. Foot, E. Levinas, D. Vokey, the analysis of the priorities of postindus-

trial and information epochs by Y. Masuda, A. Giddens, M. Castells, B.J. Kallenberg, A. Toffler, P. Drucker, M. McLuhan etc. played an important role in our research.

The most significant for understanding e-culture and existential and axiological aspects of development research by A.M. Ronchi, R. Capurro, D. R. Raban, L. Floridi, etc. deal with the study of ethical and anthropological issues of the information space. These studies influenced greatly on the author's research representing the theoretical basis for the further development of the ideas. The study of human issues, communications, cultural values, social norms, threats to an information culture are made by such scientists as Baarda, R., Rocci, L., Zhou, L., Ding, L., Finin, T., Sartor, G., Ott, M., Pozzi, F., Cockton, G. etc.

A feature of my approach to the study of electronic culture is existential-axiological research methodology. This approach allows to identify the values and intrapersonal problems of human existence, which are formed under the impact of e-culture. E-culture is considered in the framework of this approach expanded as a sphere, created with the help of digital technology.

Information technologies has greatly influenced on the development of the specific culture – electronic, digital or virtual one – within recent decades. It generates technologically and qualitatively new phenomena, involving more and more spheres, such as science, art, social interaction, education, mass media, commerce and political system. E-culture cannot be assigned to material or spiritual culture as it has features of both of them. After the creation of “the second nature” – “the world of things” a human being in actual fact created “the third nature” – the world of virtual phenomena, that is a specific synthesis of the conciseness world and advanced information technologies. The study of e-culture became rapidly important for the science and the practice as the development of new possibilities; and at the same time certain threats for existing forms and expression ways of culture appeared. At the same time e-culture also generated new values which

became higher priority for human beings nowadays and determined human world view objectives.

The analysis of the specific character of e-culture should be started with the definition of this concept, as it is polysemantic and requires its content specification. E-culture or digital culture is first of all a new sphere of the human activity, associated with the creation of the electronic copies of spiritual and material objects as well as the creative work of the virtual objects of science, communication and art (Ronchi 2009). “Electronic” means the representation in a digital form. E-culture first was mentioned at the end of the 1990s. According to the European tradition, e-culture was originally understood as a form of cultural heritage preservation (Ronchi 2009) and also as some opposition to e-commerce. Later, the term was used for the notion of different objects having electronic or other digital form. Nowadays, “e-culture” is an interdisciplinary concept having connotations in Philosophy, Cultural Studies, Sociology, Political Science, Economics and of course in the field of information technologies. Its subjects and creators are scientists, programmers, artists, representatives of mass media and average users of information systems, creating electronic forms of self-representation and self-manifestation in the global network Internet by the means of technological facilities. The most important characteristics of e-culture is transparency, globality and availability for every user; besides every subject can become both an user and a creator of its phenomena, being enough free in creative work and not having strict limitations.

BACKGROUND

E-culture comprises the following phenomena: first of all electronic forms of modern communication (Internet, cellular communication and smartphone applications, social networking sites, virtual communities, chats, blogs, web-forums, and web-sites), electronic cultural heritage (on-line museums, galleries and exhibitions), on-line

education, electronic reconstruction of cities and objects of cultural heritage in their historical and space perspective, computer games including network games, electronic mass media (on-line magazines and newspapers), digital modern art (animation, photo, cinema, music and advertizing, created by means of advanced information technologies), electronic reference systems (archives, encyclopedias, dictionaries and libraries), and information programs (security, forms of data security, etc.).

The distinctive features of e-culture are a digital form, virtuality, freedom of access, openness for the members of “information community” (those who have electronic resources), remotability, real distance from a subject, activity in accessing electronic information, possibility to participate in developing of the information content from any point of “information space”, liberality, linguistic description, absence of strict rules and norms, dominance of visual things over conceptual ones, innovativeness, technocracy, and changes of a high speed.

There are two main structural types of e-culture expression: 1. electronic form of former (traditional, classical – here not electronic) cultural objects (e.g., on-line museums, libraries, exhibitions, etc.) 2. electronic cultural objects in form and essence (computer games, social networking sites, Internet, digital art pieces, etc.)

Each of the above-mentioned types has its own characteristics, although they are formally similar and intercross. Culture, which has electronic form and essence, is the continuation and the development of the former one, having become an electronic one in its expression nowadays (to maintain its value and competitiveness).

The real “live” culture is changing in the part of traditional form to compete successfully with new electronic one. E-culture significantly turned out to be the transformation of real artifacts, ideas and creatures of human beings into virtual forms. The area where e-culture became the continuation and “shell” for “classical” (“pre-informational”) one is more than the products of e-culture and is

beyond measure. Because of it, the value of this phenomenon and the former achievements cannot be compared. The outstanding feature of the form and content of this culture is evident and is showing the pronounced tendency for extension and development of this sphere. The main space of e-culture development is the Internet, just here all of its forms are concentrated. E-culture comprises such spheres as communication, leisure and education, influencing significantly on human world view. Under the conditions of e-culture, that has been actively developing within last three decades, a new generation has already grew up having its own values, needs and ethical principles which can become an active factor of social dynamics in their turn.

EXISTENTIAL CHALLENGE UNDER THE CONDITIONS OF E-CULTURE

Anyway the world of values is associated with individuals’ desire to stabilize and prolong their being in the material and spiritual dimensions. E-culture allows a human in that to get a new form of being that is connected with information technologies and can be seen and felt. Human beings find in the virtual (online) space their “other” being, thereby, at first sight they contribute to the solving of the problem of extremity and limitation of their biosocial possibilities. Nowadays, human beings are not already “classical” *Homo Sapiens*, but this is a greatly virtualized biosocioelectronic subjects, being active both in the sphere of their physical nature, social practice and as electronic and virtual subjects, having great technological super-possibilities (crossing space-time borders and overcoming of speeds) and being a part of the global Internet community, having a demand for the virtual interaction with a nickname, electronic account, achievements and rating. The virtual alternative of human beings of the e-culture favors the development of their character features and possibilities and transforms and sublimates their real activity into a virtual one.

Human beings of e-culture spend the most part of their life in the virtual space, where they work, play, get to know new people, intercommunicate and even bury themselves. In this space personalities transform into a virtual character – an image, created by them to logging onto the Internet, where they live in an extremely dynamic sphere, requiring them to apply best efforts and mobilize the strengths and possibilities not used before. The sphere of the e-culture is a kind of the “second” life, prototype and continuation of the reality and “live culture”, where human beings of the pre-digital age searched for the solving of their existential problems: being, death, irrationality, “not freedom” and solitude.

The existence of human beings, living in the virtual space, has significant distinctions to the reality: human beings can live and die here many times, choose their presence in the Net or ignore it, specify the conditions of their being, imagine their own life story and purposes. Under my proposed approach in some specified sense the conditions of e-culture allow to find *new solutions of the human existential problems*:

“Being-towards-death” A digital form of the being becomes one more version of the existence in the world and the prolongation of human existence till the moment of the storage of the information about a subject. Nowadays more often “to be” means for a human being to be online, to have a profile, web-site, blog, etc., in such a way the information reality becomes a new kind of personal manifestation and therefore overcoming of its extremity.

“Fallenness into the world” as an impossibility to choose the conditions of the birth and the existence: In the virtual sphere the existence is determined and modeled by subjects, that involves the possibility of subjects to choose the conditions of their existence.

“Transcendence into the world”: The virtuality becomes the possibility of an individual to entrance the external world at unprecedented level, when a human being can address to millions of people

and be heard and understood. The entrance of the external space is the logging onto the Internet, joining other virtual and real participants of the interaction.

“I and Other one”: information addressing from a person to another one is conducted in new forms of multi-sided reflection when the epistolary form of the communication and existence of diary - the self-analysis (blog) becomes available for a number of people.

“Freedom” The electronic form of being offers individuals a new life world, simulated or chosen from a lot of versions by themselves. Human beings are free in such a world; they can be or not to be (log onto or out the Net at their own wishes), save or change themselves (their status, names or essence); accept or reject the terms of one or another system (a game or a social networking site); communicate or be alone; follow rules and norms or violate them.

In terms of existence, the virtuality attracts that a human being feels maximum freedom of action here and “infinite” possibilities, which one cannot achieve in the world with natural, social, and ethical restrictions. However, the online being is not real. Does it contribute to the solution of real meaningfully-vital problems in this case or help a human being to abstract from them behind the illusion of the freedom of own online image in actual fact?

I assume that e-culture gives human beings not only illusions but also favors the finding of own essence and creation of own world when they are not satisfied with real (offline) life “here and now”. Human beings still have individual decision making process under the conditions of this new being from as they can dive into new “Das man”, become the mass with specified qualities or a creator and find freedom to control the information, time, and space.

It should be noted, the conditions of e-culture (the existence of human beings “here and now”), where they find their essence, form and also *new existential problems*, challenges, that they had to face for the first time:

“Irrationality of relationship ‘virtual I and virtual Other one’: In fact, this is a new problem definition of the relationship to Other one, dealing with the communication virtualization, missing of the factor of emotional and personal perception, responsibility, honesty, etc. Under the communication virtualization, the interaction with each its part turns into a game, quasi-reality, where individuals realize that, their partners can be “any one”, even an answering machine that makes honesty, frankness, and trusting absurd.

“Loss of the reality limits”: The issue, related to the double consciousness of a human being, living in two worlds; In this regard, the offline world becomes less important, but the online one, the value of which is growing, remains to be a simulacrum, depriving a human being of “ground”.

“Virtual objectivization”: The frontier between individual and community phenomena under e-culture gets less clear. A human being is being involved into the mass more and more and becomes a part of the global network mechanism, conducting the options as many other ones according to the standard developed by a moderator.

“Freedom of online choice”: The integration with their online images, technologization of human beings, results in multi-alternative and pluralistic models of behavior, the moral regulator of which are replaced with anarchy, “instructions” or “game rules”; Ethical choice is extremely hampered and transferred from the sphere of moral appraisal into the sphere of personal and moral self-evaluation in full.

“Solitude in the Net”: The issue of loss of the interpersonal communication, dipping into the Internet-space, where everybody exists alone with a machine; The alienation of human beings from traditional grounds: nature, family, school, friends, which play less significant role, turning a person into a biosociovirtual “monad”.

“Online not liberty”: Within information environment human beings find new liberties and dependences. The main one of them (from e-culture) is the striving to be all the time online, the fear of the reality and interpersonal communication, and loss of interest in the life.

Particularly, the urgent problems has turned to be related with the development of new not liberties of the information age. Within a given context the following examples can be given. Thus, the neurologist P. Whybrow compares computer dependence with drug addiction and notes that computers intensify the excitement and enhance depressions of users at the same time: “The computer is electronic cocaine for many people. Our brains are wired for finding immediate reward. With technology, novelty is the reward. You essentially become addicted to novelty” (Whybrow 2012).

The Internet-dependence represents with the development of human aspiration to be online, interaction with online partners and online game obsession, and as consequence the disregard to own health, offline social relationships, reduction of cognitive and creative activities, and intensification of reality perception form when one perceives the information and does not process it. The serious risks involve the transferring of values into online world, social networking sites, hindering offline communication and the ability to solve life problems and enhancing destructive thinking and self-destructive behavior. In China, South Korea and Taiwan the internet-dependence is recognized in medical science as a disease and the Internet dependence is considered as a nationwide crisis. In these countries tens of millions people are considered to be Internet-dependent.

It should be noted, Internet-dependence is both psychological and existential issue, as it makes human beings feel themselves incomplete and “disabled” offline. Gamers or active users of social networking sites can get the feeling of being fullness only online, the reality is not important for them.

The perspectives of these changes can result in the further tendency when a person turns into any “superhuman”, existing in offline and online worlds, and loses emotional and sensorial sphere, demand for reflection and meaningfully-life search. The existential problems and risks get new forms, breaking down the reality boundaries for

human beings and degrading their uniqueness at the same time.

The overcoming of the solitude and the insulation of personal existence involve the human possibility of communication and transcendence to other one through love, friendship, empathy, and sympathy. E-culture produces new possibilities for the communication of new global type and human interaction without boundaries which have never existed before. Online communication has united the milliards of people nowadays. According to some estimation over 2 billion people from every country and continent are online at the same time. Of course, this unity cannot be compared with real communication; however, it is impossible and even dangerous to ignore this fact. Neglecting of the role of online communication and online communities can result in the estrangement of parents from their children, facilitate the breaking off between online and offline relationships, contribute to the extension of crisis of human social identity. It should be pointed out that a large number of people consider the Internet is an important form of the communication and interaction.

The virtualization of the communication sphere and social interaction is probably an area of the highest risk under the information age that contributes to the changing of personal essence, the forms of experience transfer existing for millenniums, traditions, and values.

The shift from the personal communication to the communication mediated by information technologies becomes a new condition of the development of modern human beings, who overcome age-related, psychological and physiological complexes within the communication on the one hand and can get new phobias and fears on the other hand. Thus, modern psychologists diagnosed nomophobia as a social fear of the direct interpersonal communication caused by the habit to use the computer-aided or cellular communication (King 2013).

The interpersonal communication is more replaced with its online simulation, displacing such the most important relationship spheres as love

and friendship. Modern researchers note that the number of network romantic relations has been increased, and virtual relations (called “the Second Life”) sometimes can improve the mental state of persons, help to solve their real problems (Golbert 2011). The concept “friendship” is undergoing certain changes under e-culture, dealing with the loss of stability, social and financial support, and responsibility (Amichai-Hamburger 2012). The simulation of feelings in these spheres facilitates the loss of human existential grounds and changes moral and ethical milestones related to the understanding of Other one’s value.

In some specified sense, human beings live in two worlds, which they do not trust in full; offline communication remains to be important, although the value of virtual Other one is developing, the interaction with who has its rules. The logging onto Net to “meet” Other one, and transcending under these conditions turns out to be insignificant, senseless, as these relationships involve the simulation of feelings, trusting, understanding, and participation in Other one’s life.

INFORMATION FREEDOM

Freedom remains to be the most important existential value of a person. The UNESCO Code of Ethics for the Information Society (2011) was developed for the absolute guarantee of the rights and the freedom of a person in the information society. Has a human of the Information Age become freer in such a way?

On the one hand, new technologies make possible high-speed and high-precision processing of the information, discharging a human from the necessity to do routine activity. Thus, it seems, a person has more free time, but in fact a modern human spends this free time for new activities, involving (a) maintenance of information systems (development and installation of new software programs, fight against viruses, protection of data and failure recovery), (b) implementation of volume of work increased in conditions of

information boom, (c) uploading and downloading of data and their reprocessing, (d) search of necessary information and check of its validity, (e) processing of increased flow of documents, high tech innovations, etc.

Nowadays a modern specialist should have more competencies (language, intercultural, information and other competences), than last years and centuries, and much of free time is spent for the development of this knowledge and these skills. In its turn, it requires new methods of training, extension of professional skills, especially for brain workers, HR managers and workers, dealing with information processing (Hemingway & Gough, 2000). During the development of information facilities a person more often spends time to achieve a high level of high technologies. Human beings are developing together with them, in which case they are becoming unfreer in their activity.

What are the perspectives of freedom development in the Information Age? Information first of all has provided us with significant freedom for obtaining of information which should not be underestimated. That, what was earlier limited and was represented only for professionals, became available to the wide public. Politicians, businessmen and community leaders have to regard, that their acts have not already been confidential and evoke a broad public response at once. In this case the quality of information and messages, presented by mass media, has sharply become lower. Information is full of plagiarism, unverified and unconfirmed facts. There are almost no prohibitions and taboos for the modern society of information freedom. Alistair Duff emphasized the situation of “normative crisis”, that is characteristic for the information society, where traditional norms have not already been effective, but new principles have not formed yet (Duff 2008). It veils one of its main dangerous tendencies. Risks and instability, produced by achieved freedom, are growing and result in instability, chronic crisis and bifurcation of the system. A new factor, that can break fragile peace and agreements, can appear at any moment of such system development. The

maximum of freedom involves a high degree of responsibility and morality, though the last ones, as we have found out, are not valuable priorities of the new world.

Electronic credit cards, identification documents both are becoming opportunities for more freedom in the activity and produce new nonliberties for a person. As Simon Rogerson pointed out, human beings, not having such choice, cannot feel themselves comfortable in the modern world as nowadays their personalities exist in two levels: physical and electronic ones (Rogerson 1998).

Freedom for new generation became the main achievement and welfare, but during its realization, the issue of sense and purpose of its use arose more acutely. Freedom that has been understood as the end in itself for a long time became a value and a facility during its implementation to achieve something else. Now freedom represents a value as a constant selection opportunity, where it is important not so much direction and result of a choice, as the state of choosing. Freedom of choice is realized during consumption of goods, in communication with other people, as an opportunity of moving in space and a choice of leisure, education, etc. The availability of freedom does not still mean its high function by itself. Freedom can turn out to be not a form of self-development or moral development, but only a choice of one commodity from many ones. The freedom of the information society is an opportunity to achieve a specified purpose; however, technologies do not set these purposes.

FUTURE RESEARCH DIRECTIONS

Further research of this topic related to the study of such phenomena and the problems of virtual communication, ethics in the electronic culture, the problem of preservation of identity in the information world. The main current trend of the modern society encompasses the decline of the role of the traditional (real) and distant-traditional communication and the increase of the value of the

distant-nominal communication. As characteristic features of the distant-nominal communication, the special attention to the Ego demonstration, the continuity of the virtual communication, “radio effect”, weakening of emotional communication, formation of the need to keep the virtual communication turning sometimes into addiction, the simulation of real relations and decline in trust. As the result, the real life has been virtualized.

The ethics and etiquette of the virtual communication have still been “devised”. The external processes of the regulation of the ethical principles of the information society (In this case, it is necessary to recognize the leading role of UNESCO) and the self-organization projects (i.e., design of ethical standards in virtual communities), have taken place. Virtual communication does not change the people’s ideas of moral values but facilitates their attenuation and transformation into “relicts” of the traditional reality in view of the simulation and game character and of reduced society control. The strict arrangement of the virtual content and its subjection to the proposed codes inevitably will produce the aspiration to escape from the regulations therefore the censorship development will not resolve this problem. In this author’s view, the educational system and cultural life in the information world needs to contribute to the socialization of people and their adaptation to new technological conditions without losing sight of social attributes to be effective.

CONCLUSION

Thus, e-culture does not replace the original things and should not oust them completely. The former classical, “live” culture is passing in large part through the crisis dealing with the loosing of spiritual values in the age of consumption because of electronic culture. Its innovative form attracts a present-day’s person and in such a way continues developing. In such a case, it is important to understand that this form does not replace but

develop and upgrade cultural heritage allowing it to be available and preserved for descendants. E-culture is not only the duplication of “live” culture, but also new achievements done by the application of creative high technologies that provided radically new facilities and trends of the self-expression, cognition, and development. The electronic resources multiply the abilities of human beings and give them new liberties and new life world. In this regard, the transition from the real sphere of the interaction into the virtual one reduces the importance of the interpersonal communication, moral and ethical norms, and traditional life forms. The e-culture development in the existential contexts should be referred to the most important ones: the development of a human value of a new type – virtual existence; the development of e-culture, contributing to the solution of personal existential problems (death, solitude, not-liberty) within virtual “being here”; the technocratization and virtualization of human beings themselves, intergrowing with information systems and getting super-possibilities in exchange for the freedom in terms of existence; the deepening of existential vacuum under the virtualization of culture and human beings, coming from the loss of the reality boundaries, the virtualization of human beings’ essence, losing the real identity with the social world (socium) (and several its groups) in exchange for the identity with virtual groups, images, and Technologies; the reduction of the importance of the role of real interpersonal communication, being a traditional basis of personal being, shift to the communication, and mediated information space; the development of new ethics in the field of e-culture and e-communication, where axiological pluralism becomes a new challenge to the moral behavior of individuals.

The changes, that culture and the sphere of human being are undergoing nowadays, require to be studied in details as the direction of the further subject’s activity in the nature and the society, multiply increased by the facilities of high technologies.

KEY TERMS AND DEFINITIONS

Digital Information And Virtual Communication: Is the communication form between people by means of information technologies at remote distances with the following features: global character, the self-organizing network

form, the spontaneously formed diverse content, simultaneous participation of a great number of communication subjects, impersonal nature, possibilities of anonymous interaction, coexistence of real interpersonal communications, and artificial simulacrum (nominal) relations.

E-Culture Culture or Digital Culture: Is a new sphere of the human activity, associated with the creation of the electronic copies of spiritual and material objects as well as the creative work of the virtual objects of science, communication and art.

Ethics of Information Society: Ethical principles, norms, rules of behavior of people in the conditions of a virtual form of communication (the Internet, games, mobile communication, etc.), directed on formation of valid, humane, legal space for communication.

Transcendence Into the Virtual World: Is the process of entrance of identity in the information interaction in the use of digital technology, which creates a feeling part of the whole transpersonal. The entrance of the external space is the logging onto the Internet, joining other virtual and real participants of the interaction.

Types of e-Culture Expression: 1. electronic form of former (traditional, classical – here not electronic) cultural objects (e.g., on-line museums, libraries, exhibitions, etc.). 2. electronic cultural objects in form and essence (computer games, social networking sites, Internet, digital art pieces, etc.).

Virtual Objectivization: blurring the boundaries between personal and social phenomena in a virtual interaction that converts human values and outlook

Virtualization: Is the process when the real processes and phenomena are replaced by the virtual forms. On the one hand, it deals with the creation of digital analogs and simulations of the real culture objects and on the other hand, it deals with the creativity of the new cyberspace and its phenomena.

The Fundamentals of Human-Computer Interaction

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

As modern technologies continue to develop, the ability of users to interface with new computer systems becomes a paramount concern (Information Resources Management Association, 2016). Human-computer interaction (HCI) is a field of research that develops the advanced activities of user-computer interaction (Anishchenko, Osinov, & Shaposhnikov, 2011). HCI has been the focus of attention for researchers in the past decade, with considerable work being done in the various modalities for communicating with the computer (Reddy & Basir, 2010). HCI studies play an important role in the design, implementation, and evaluation of a new generation of graphical user interfaces designed to support consumer behaviors and information needs (Servidio, Davies, & Hapeshi, 2016).

Humans are limited in their capacity to execute the information. This perspective has the important implications for the interaction design. Information is received and responses given via a number of input and output channels, such as visual channel, auditory channel, haptic channel, and movement. A primary goal of virtual environments is to support the efficient, powerful, and flexible HCI (Devyatkov & Alfimtsev, 2013). A computer system comprises various elements, each of which affects the user of the system. Input devices for interactive use, allowing text entry, drawing, and selection from the screen. Output display devices for interactive use: different types of screen mostly using some form of bitmap display; large displays and situated displays for shared and public use; and digital paper may be usable in the near future.

The interaction takes place within a social and organizational context that affects both user and system. Iterative design practices work to incorporate crucial customer feedback early in the design process to inform critical decisions which affect usability. Interaction models help practitioners and researchers understand what is going on in the interaction between user and system. Many interfaces, relying on body gestures (Liu & Jia, 2004), speech (Green & Eklundh, 2003), and brain computing (Mason & Birch, 2003), have been proposed or developed which assist humans to interact with robots in a more intelligent and natural activity. Various interaction techniques have been developed for interactive 3D environments (Jankowski & Hachet, 2015).

This article aims to bridge the gap in the literature on the thorough literature consolidation of HCI. The extensive literature of HCI provides a contribution to practitioners and researchers by explaining the fundamentals of HCI in order to maximize the impact of HCI in global operations.

BACKGROUND

HCI emerged as a distinct research discipline in the late 1970s and early 1980s when monitors and workstations became available and opened up the use of computers to non-engineers (Grudin, 1990). In the 1990s, network technology and mobile devices broadened the scope of research beyond the individual user and personal computers (Hollender, Hofmann, Deneke, & Schmitz, 2010). HCI should be designed to be effective, efficient, engaging, error tolerant, and easy to learn (Fall-

DOI: 10.4018/978-1-5225-2255-3.ch364

man, 2010). With the development of computer vision technology, researchers have studied a lot of HCI methods to replace the keyboard and mouse (Juan, 2012).

Major HCI research areas comprise theories and models of human behavior when interacting with information technology (IT), general or more specific guidelines or heuristics for the design and evaluation of IT, methods for the user-centered development of IT, and the development of new interaction paradigms (Preece, Sharp, & Rogers, 2002). Interaction models address the translations between what the user wants and what the system does. Ergonomics looks at the physical characteristics of the interaction and how these influence its effectiveness. The dialog between user and system is influenced by the style of the interface. Examples of effective strategies for building interactive systems provide paradigms for designing usable interactive systems. The evolution of these usability paradigms also provides a good perspective on the history of interactive computing.

Different HCI techniques and technologies with different design criteria have been developed for several decades (Rantanen, Niemenlehto, Verho, & Lekkala, 2010). Interaction design is about creating interventions in often complex situations using technology of many kinds including PC software, the web, and physical devices. Usability is key to the success of any interactive system—from commercial software to business-to-business (B2B) websites to the handheld devices (Rosson & Carroll, 2001). Promoting consistency in user interface and application design remains a prominent practical issue (Nielsen, 1989). Software engineering provides a means of understanding the structure of the design process, and that process can be assessed for its effectiveness in interactive system design. Designing for maximum usability is the goal of interactive systems design. Evaluation tests the usability, functionality and acceptability of an interactive system.

THEORY AND APPLICATIONS OF HUMAN-COMPUTER INTERACTION

This section emphasizes the overview of HCI; cognitive models, socio-organizational issues, and stakeholder requirements; HCI and hand gesture recognition; and the multifaceted applications of HCI.

Overview of Human-Computer Interaction

With the advancement of technologies, a computer system has become a very powerful machine which has been designed to make the human beings' tasks easier (Sharma & Verma, 2015). The power of computers begins to be exploited in subjective areas of human study like those related to human psychology in order to make the interaction between humans and computers more natural (Choubey & Singh, 2012). To achieve the effective HCI, the computer should be able to naturally interact with the user, similar to the way that HCI takes place (Sebe, Cohen, Cozman, Gevers, & Huang, 2005).

Defining what, how, when, and why to build computer resources with accessibility features is one of the main concerns of the HCI area (Peres, Boscarioli, Bidarra, & Fantinato, 2012). HCI pervasively exists in the individuals' daily lives (Yeo, Lee, & Lim, 2015). From an applied perspective, technological advances have changed the way that humans interact with their computers (Posard, 2014). The application of HCI principles are frequently successful in increasing user satisfaction and engagement with an interface (Wohl, Parush, Kim, & Warren, 2014). The correct functioning of interactive computer systems depends on both the faultless operation of the device and correct human actions (Curzon, Ruksenas, & Blandford, 2007).

More natural and comfortable HCI methods are the goal of several research efforts (Tang, Chen, Zheng, Han, & Li, 2015). Traditional methods

in gesture recognition are based on visual sense (Munoz-Salinas, Aguirre, & Garcia-Silvente, 2007), wearable devices or a combination of the two (Cheng, Xie, Bian, & Tao, 2012). Benefits of utilizing the visual sensing include the passive detection, non-contact, and freedom of movement (Tang et al., 2015). As a human body in motion becomes electrostatically charged through contact and friction charging (Cross, 1987), the resultant change of the electrostatic field enables an indirect measurement of body movement.

Many researchers measure electrostatic signals during walking with the measuring device on the body (Ficker, 2006) and utilize the non-contact method to measure the human body's electrostatic signal (Kurita, 2011), particularly the electrostatic signal generated from walking (Takiguchi, Wada, & Toyama, 2008). Evolutionary visual software analytics is the process for supporting software maintenance, with the active participation of users, through the understanding and comprehension of software evolution by means of visual analytics and HCI (Gonzalez-Torres, Garcia-Penalvo, & Theron, 2013). The visual representations of huge datasets supported by browsing and navigation capabilities are challenging due to the limited size of screens (Leung & Apperley, 1994).

The design of visual representations uses the linked views and interaction mechanisms to allow the exploration of details while keeping the context (Hornbaek & Hertzum, 2011) and allows the tracking of relationships to facilitate the interpretation of specific elements. Interaction design patterns has been designed for the repeatable solutions in interface and interaction design (Tidwell, 2011) and several researches has been conducted on visualization design and HCI. Radio frequency identification (RFID) tags have been used by several researchers as a key component for HCI in a computer-augmented environment (Nishi, Sato, & Koike, 2001). RFID solutions can be utilized to reduce the operating costs through decreasing labor costs, enhancing automation, improving tracking and tracing, and preventing the loss of materials (Kasemsap, 2015a).

Cognitive Models, Socio-Organizational Issues, and Stakeholder Requirements

A cognitive model is an approximation to animal cognitive processes (predominantly human) for the purposes of comprehension and prediction. Cognitive models can be developed within or without a cognitive architecture, though the two are not always easily distinguishable. Cognitive models tend to be focused on a single cognitive phenomenon or process (e.g., list learning), how two or more processes interact (e.g., visual search and decision making), or to make behavioral predictions for a specific task or tool (e.g., how instituting a new software package will affect productivity). Cognitive models represent users of interactive systems. Hierarchical models represent a user's task and goal structure. Linguistic models represent the user-system grammar. Physical and device models represent human motor skills. Cognitive architectures underlie all of these cognitive models.

There are several organizational issues that affect the acceptance of technology by users and that must be considered in system design: systems may not take into account conflict and power relationships; those who benefit may not do the work; and not everyone may use systems. HCI designers must identify specific stakeholder requirements within their organizational context. Socio-technical models capture both human and technical requirements. Soft systems methodology takes a broader view of human and organizational issues. Participatory design includes the user directly in the design process. Ethnographic methods study users in context, attempting to take an unbiased perspective.

Human-Computer Interaction and Hand Gesture Recognition

Various approaches to HCI have been proposed in the last few decades as an alternative to the classic input devices of keyboard and mouse (Kiliboz

& Gudukbay, 2015). The touch panel and voice control are the most new input devices for HCI (Hsu, 2015). Human hand recognition plays an important role in a wide range of applications ranging from sign language translators, gesture recognition, augmented reality, surveillance, and medical image processing to various HCI domains (Bilal, Akmeliawati, Shafie, & Salami, 2013). Hand gesture recognition is widely used in many applications, such as in computer games, machinery control (e.g., crane), and mouse replacement (Hasan & Abdul-Kareem, 2014).

HCI with hand gestures plays a significant role in these modalities because humans often rely on their hands in communication or to interact with their environment (Kılıboz & Gudukbay, 2015). Hand-gesture-based methods provide the natural way of interaction and communication (Pavlovic, Sharma, & Huang, 1997). Many studies evaluate the gesture-based interaction techniques, and propose the useful ways to increase their effectiveness (Rautaray & Agrawal, 2015). On the human side, system performance is limited by the cognitive and motor processes used for gesture formation (Rempel, Camilleri, & Lee, 2014). On the computer side, system performance is limited by the rate and fidelity of gesture capture and processing (Rempel et al., 2014).

Multifaceted Applications of Human-Computer Interaction

The computers are social actors (CASA) effect refers to the application of social rules when individuals interact with computers (Liang, Lee, & Jang, 2013). Speech emotion recognition (SER) represents one of the emerging fields in HCI (Ramakrishnan & El Emary, 2013). Emotion plays an important role in the interaction with users and computers (Park & Kim, 2015). Speech technology plays a central role in enhancing HCI, especially for small devices for which graphical user interface has obvious limitations (Deng & Yu, 2005).

Lee (2008) also found that people adhere to the recommendations from a male-voiced computer more than a female-voiced computer, reflecting gender stereotypes.

Regarding the proliferation of the low-cost vision sensors, embedded processors, and efficiency of wireless networks, a large amount of research has focused on the utilization of multiple sources of information for the analysis of behavior (Garcia-Rodriguez & Garcia-Chamizo, 2011). This perspective has the potential applications, such as human-computer interfaces to virtual reality, gaming, gesture-based control, presence detection, and event intelligence applications for human-centric applications, such as the detection of falls in care of older people (Garcia-Rodriguez & Garcia-Chamizo, 2011). Researchers have examined the role of mindlessness during HCI (Liang et al., 2013).

Nass and Moon (2000) identified four perspectives of general responses when individuals interact with computers: the overuse of human social categories (e.g., applying gender stereotypes to computers); the exhibition of overlearned social behaviors (e.g., reciprocity and politeness); the demonstration of premature cognitive commitments (e.g., specialist television perceived as having better content than a generalist television set); and the alteration of responses to a given computer personality (e.g., participants responded to computers when the communication style from the computer matched versus mismatched participants' personality). Many researchers examine the effects by altering the nature or content of computer feedback (Liang et al., 2013). Mindlessness occurs even when computer agents display more human-like cues (Lee, 2008). Recent research extends the CASA effect to the interaction with computer agents on websites (Karr-Wisniewski & Prietula, 2010). The cognitive deficit approach treats mindlessness as an inability to process information due to the presence of competing cognitive demands (Lee, 2010).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of HCI will provide the potential opportunities for future research. The Internet of Things (IoT) is the growing range of everyday objects acquiring connectivity, sensing abilities, and increased computing power. Cloud computing includes network access to storage, processing power, development platforms, and software (Kasemsap, 2015b). Wireless sensor networks (WSNs) consist of many small, resource-constrained sensor nodes together with several base stations. WSNs can combine the objective physical world and the logic information world together, toward enhancing the utilization of robots. The benefits of robots has increased their flexibility with being capable of performing a variety of tasks and applications. Regarding robotics, robots can allow for increased production and profit margin because they can complete tasks faster. HCI, the IOT, cloud computing, WSNs, and robotics are remain important issues for future research directions.

CONCLUSION

This article highlighted the overview of HCI; cognitive models, socio-organizational issues, and stakeholder requirements; HCI and hand gesture recognition; and the multifaceted applications of HCI. HCI is characterized as a dialogue or interchange between the human and the computer because the output of one serves as the input for the other in an exchange of actions and intentions. HCI is a sociotechnological discipline whose goal is to bring the power of computers and communication systems to people in ways and forms that are both accessible and useful in the effective manner. HCI involves the activities of humans using computers. A basic goal of HCI is to improve the interactions between users and computers by making computers more usable and receptive to the user's needs.

HCI encompasses not only ease of use, but also new interaction techniques for supporting user tasks, providing better access to information, and creating more powerful forms of communication. HCI involves input and output devices and the interaction techniques that use them; how information is presented and requested; how the computer's actions are controlled and monitored; all forms of help, documentation, and training; the tools used to design, build, test, and evaluate user interfaces; and the processes that developers follow when creating effective human-computer interfaces.

HCI addresses the design, evaluation, and implementation of interactive computing and computing-based systems for the benefit of human use. HCI plays an important role in identifying the environmental and social issues which can affect the use of systems, and providing techniques to ensure the design of the system will be usable, effective, and safe. HCI draws on computer science, computer and communications engineering, graphic design, management, psychology, and sociology as it tries to make computer and communications systems ever more usable in executing the tasks. HCI is an important consideration for any business that uses computers in their everyday operation.

KEY TERMS AND DEFINITIONS

Communication: The exchange of thoughts, messages, or information, as by speech, signals, writing, or behavior.

Computer: The device that computes, especially a programmable electronic machine that performs the high-speed mathematical operations.

Gesture: The expressive movement of the body, or something that is done to show a feeling.

Information: The data that can be stored in and retrieved from a computer.

Information Technology: The development, installation, and implementation of computer systems and applications.

Interaction: The situation in which two or more objects act upon one another to produce a new effect.

Software: The programs and routines for a computer or the program material for an electronic device which make it run.

Software Engineering: The process of making, testing, and documenting computer programs.

Technology: The scientific method and material used to achieve a commercial or industrial objective.

H

Interface Trends in Human Interaction, the Internet of Things, and Big Data

William J. Gibbs

Duquesne University, USA

INTRODUCTION

The Web and other networked-based services are primary vehicles for news and information dissemination. In 2008, Kohut, (2008, p. 21) reported that, “Thirty-seven percent of people today, including more than half of Internet users, obtain news online whereas ten years ago only 13% of the public and 35% of Internet users went online for news.” More recently, Conaghan (2015, p. 1) noted that greater than 93% of men and 92% of women between the ages of 25-44 who went online in August 2015 engaged with newspaper content and half of this online audience use mobile devices (smartphones or tablets) to get news. A majority of major news websites are finding that most of their traffic comes from mobile devices rather than from desktop computers (Mitchell, 2015). Due in large part to mobile connectivity, people can obtain news instantaneously and become aware of worldwide events at any time of day or in any location around the world. It is estimated that there are over 7 billion mobile-cellular subscriptions (ICT, 2015), which enable people to access the news wirelessly on mobile devices, making news and information services portable, personalized, and participatory (Purcell, Rainie, Mitchell, Rosenstiel & Olmstead, 2010). The transformations taking place in news and information services magnify questions regarding the influence networked-based services have on newsreaders (Santana, Livingstone, & Cho, 2011). Researchers indicate that media are not solely transmitters of information, but they influence the process of thought (Carr, 2008; Purcell et al., 2010).

Online news content is frequently represented on digital displays as a highly dynamic interface characterized by a proliferation of media and interactivity that supersedes what is found in traditional informational sources such as newsprint or television news. Digital interfaces or points-of-contact through which people experience news and information services have never been so diverse or transformative. They present complex visual landscapes comprised of and supported by multimedia, communications, and networking technologies. Pervasive worldwide, they afford people an unprecedented degree of functionality and access to news, information services, and other people. The actions or ways in which users interact with modern interfaces are diverse and include behaviors such as swiping, scaling, dragging scrolling, hovering, and flipping (Sundar, Bellur, Oh, Xu & Jia1, 2014). Interfaces are a foundational technology that has helped instigate tectonic shifts in news and information consuming behavior, journalistic reporting, and news preparation and distribution, the impact of which is not fully understood.

In this chapter, I examine trends in today’s news-orientated interfaces and the impact of digital interfaces on news consumption. Digital interfaces will be differentiated from traditional informational sources such as newspapers and television news. Additionally, I will explore several major characteristics or trends germane to today’s news interfaces and their implications for how people consume news and, more generally, for how they transform information services: a) rapid innovation, b) interactivity, c) social, d) standardization, e) scale, f) media convergence and, g) the Internet of Things and Big Data.

DOI: 10.4018/978-1-5225-2255-3.ch365

TRADITIONAL MEDIA FORMS

Access to the news and one's understanding of it are influenced by interface elements. When people have contact with news, news organizations preplan or design the visual, auditory, conceptual, and functional aspects of that experience or point-of-contact. The manifestation of this design comprises an interface intended to help people access news and derive meaning from it. For example, when reading a newspaper, the printed document, type, content organization, headings, writing style, the proximity of page elements, the surrounding context, groupings and placement, and page numbering establish a context that guides readers' attention and provides them information about how to use the newspaper to glean information. One can imagine how readers would fare if a paper suddenly removed all headlines, page numbers, table of contents, and used disparate type. Some authors contend that the typographical design of newspaper makes reading easier and enhances comprehension relative to news content published on the web (Shafer, 2011). The inherent attributes of newsprint and television news media greatly influence how people access and comprehend news as well as how news is reported. Pippas, Walter, Endres, and Tabatcher (2009), for example, report research showing that content recall for television and radio news was lower than recall of textual information. Santana et al. (2011) found that news consumption varied based on the frequency, duration, and visual content of a news presentation. Access to a news story and learning from it is directly affected by many contextual features that make up the social and behavioral state of the environment in which a person acquires news (DeFleur, Davenport, Cronin, & DeFleur, 1992, p. 1011).

Characteristics of Television and Newsprint

Television broadcasts provide a vastly different news gathering experience compared to newsprint

and online news. People adapt their behavior to accommodate the differences. A person may view a TV news broadcast in a room with other people or while engaging in some other activity. Television is a passive medium wherein viewers watch and listen as content gets delivered to them. They have limited physical engagement with the display interface as they endeavor to get news. A distinct separation exists between news content and the television interface. Broadcasts present short video-based stories sequenced linearly within a specified timeframe at a fixed location for on-air viewing. One's access to and the sequencing of such stories is controlled by the news organization. People can record TV broadcasts for archival purposes. Once recorded, the broadcast can be controlled by the individual.

Newspapers, unlike TV and radio broadcasts and online news, are tangible, highly portable, and can be easily archived by the reader. Although, today's mobile devices, web interfaces, and associated networking technologies, increase the portability of TV and radio broadcasts as well as online news. However, unlike newspapers, online content, while recordable, often requires software and hardware for recording or downloading. As people acquire news, there is a high degree of physical interaction with the printed medium or interface. The interface and content display are malleable - as people touch it, the display of content changes. Newspapers afford in-depth reading as well as active information search. Readers control the access to information. They navigate the printed document linearly or non-linearly, depending on their preference. News content is presented primarily as text and it is usually more in-depth compared to broadcasts that use visual and auditory stimuli to underscore messages. With newsprint, people bring established attitudes about what to expect and knowledge of newsprint conventions. Additionally, newsprint has a sense of permanence unlike online news, which is transient in that it appears and disappears without notice (Santana et al., 2011). Similarly, TV news broadcast are temporary unless recorded, but they

do have a scheduled broadcast times so they do not appear without notice. Moreover, compared to online news, newsprint often gives readers more informational cues about the magnitude of a story, which may assist readers in story selection (Santana et al., 2011).

Newspaper and television news organizations excel at providing consumers sophisticated interfaces (points-of-contact) that, by-and-large, engender meaningful and efficient access to news. As news organizations evolved, interfaces have become customary with designs grounded firmly in established conventions or rules for type, placement, content organization, and layout, among others. Conventions for newsprint, for instance, date back hundreds of years. Consequently, when people experience or have contact with news, they find much commonality in how different news organizations report, broadcast, or print it. Moreover, the interface is familiar. For the most part, news consumers, with minimal mental or physical effort, can effectively access news content in newspapers or on television any given day from almost any news organization. From a consumer perspective, the adherence to convention and ensuing commonalities among interfaces (points-of-contact) are advantageous because they make news accessible and potentially more comprehensible.

CHARACTERISTICS OF ONLINE NEWS INTERFACES

The interfaces or points-of-contact in the digital realm are fundamentally different from those of traditional newsprint and television. Now, between the user of a device and the information or service he/she seeks is a computational or digital interface encompassing the hardware and software components that users see, hear, touch, or talk to as they interact. Digital interfaces are becoming a dominant means of access as people retrieve news on websites, news feeds, or podcasts using computers, phones, or a host of other devices.

Correspondingly, broadband, broadcasting, and information technologies enable news networks to deliver multimedia content (voice, imagery, video, and computing) and to support multimodal human-computer interactions (e.g., touch, speech) in a single interface across many different types of devices.

News interfaces have emerged as amalgamations of visual and information design, multimedia content, tools, and functionality that afford unparalleled connections among content, services, and people. For instance, reading news stories, one can easily link to related stories, post comments, or participate in social network services. The interfaces of all major online networks give access to services, such as Twitter and Facebook. During many recent political upheavals and crises, news interfaces gave people instantaneous, global access to breaking newsworthy information by way of a single display.

Transformations in news and information services brought about by rapid and pervasive technological advancements impact, among other things, news literacy, the types of news sources being used for news, reporting approaches, and how people read and experience news. Today's communication devices and interfaces are diverse, complex, and seemingly ever evolving. Compared to newsprint and television broadcast, digital interfaces are distinct in many ways, several of which are presented in Table 1. In the following sections, characteristics or trends related to news interfaces are presented.

Rapid Innovation

Innovation in the realm of digital interfaces occurs rapidly. As new organizations discern industry trends, their interfaces change often (unexpectedly) and they have given increased prominence to personalized and social services (e.g., discussing news stories, contributing news), seemingly without regard to the needs of users or the service quality they encounter at the interface level. It is not uncommon for the entire design of a news

Table 1. TV, newspaper, digital interface characteristics

	TV	Newsprint	Digital
Access to content	Linear	Nonlinear	Nonlinear
Control of content presentation	News Organization	Reader	Reader/User
Content type	Non-static: video, audio, images, graphics, text, animation	Static: Text, images, graphics	Non-static: video, audio, images, graphics, text, animation
Scale	Fixed, clear delineation of beginning/end	Fixed, clear delineation of beginning/end	Not fixed, no beginning/end, little sense of scale
Content updating	Daily; continuous for 24 hour news	Daily	Continuous; dynamic
Distribution medium	Television	Printed paper	Multiple electronic devices
Interactivity	Low	Low-Moderate	High
Portability	Moderately portable, with player or devices	Highly portable	Portable with mobile devices
Viewport variations	Moderate	Moderate	High
Content Adaptation to Viewport	Low	Moderate	High
Archiving by user	Moderate: User records	User stores paper	Moderate
Tangibility	Low	High	Low
Functionality	Low	Low	High
Affords socialization	Low, tangential socialization	Low	High, virtual socialization
Big Data and Analytics	Low	Low	High

website to change with new, sometimes arcane features, functions, and controls added. The extent to which website interfaces support or impede users' access to news content, while organizations keep pace with industry trends, is unknown. The impact on people, news consumption, the user experience, and trust in an organization is also largely unknown. How and why decisions to change interfaces or adopt news interface technologies are made is critical to understanding emergent interfaces and their impact on news distribution and consumption. For example, targeting advertisements and stories to users based on their interests is common and seemingly done in the interest of improving the user experience. However, these efforts often impede the experience one has at the interface. Advertisements consume the screen, taking control of the interface even briefly. When reading a story, it is not uncommon for content to shift vertically to accommodate ads as the pages refresh, interrupting reading as one's eyes traverse lines of text. Video ads auto start often resulting in multiple audio tracks playing simultaneously.

The evolution and maturation of interface technologies greatly influence news consumers' information seeking behavior. Additionally, as interfaces change, becoming more sophisticated and technically complex, particularly back-end technologies, news organizations are faced with many new questions concerning interface design, development, and implementation and who or what drives interface technology decisions, the news organization, journalists, editors, advertisers, technology or technologists.

Interactivity

Digital interfaces represent a highly dynamic point-of-contact characterized by a proliferation of motion and static media and interactivity that supersedes what is found in either traditional newsprint or on television. A significant issue posed by hypermedia environments such as the web is effectively dealing with complexity and not overwhelming users with information and

functions (Vaughan & Dillon, 2006). While highly dynamic, feature-rich interfaces are pervasive, they may prove too complex for users. A premise of the cognitive information processing model of cognition holds that humans have limited cognitive capacity. Complex tasks performed with visually intensive and dynamic interfaces may consume cognitive resources and cause cognitive overload, diminishing meaningful processing (Smith & Ragan, 2005). Opgenhaffen and d'Haenens (2011) point out that news content with features such as multimedia, interactivity, and hypertext may be overly complex and consume more cognitive resources than users have available, resulting in cognitive overload. They found that "cognitive load plays an important role during information processing and that the form of the medium can impact this mental load. (p. 20) Moreover, Santana et al. (2011) reported that users are disinclined to engage with multimedia tools, preferring first the text of a story instead. Berry (1999) found that in terms of comprehension and information recall, multimedia did not make a difference.

To effectively interact with today's interfaces, one must understand a host of interaction conventions such as the magnifying glass icon indicating search or what is colloquially known as the hamburger icon representing hidden menu items. Icons comprise a visual language that is often misinterpreted and used inconsistently across sites or applications. The placement of interaction objects and their proximity to one another is also meaningful, as location in a display conveys purpose and hierarchy. For instance, websites designed for desktop computers typically orient primary navigation horizontally at the top of the page with secondary navigation located immediately below or oriented vertically on the left side. People come to know that these regions of the display serve as navigation. However, on responsive sites, the interface adjusts to the size of the viewport. Due to the limited screen space on mobile devices, navigation regions may get hidden or oriented differently compared to when the site is viewed on a desktop computer. Thus,

the placement of navigation and content alter depending on the device being used. Given that many people use multiple devices simultaneously, such differences at the interface add complexity and potentially diminish the user experience. In addition to the aforementioned factors, navigational structures vary. The New York Times home page, for instance, presents a hierarchical structure from which users drill-down to access content. USA Today presents a flat structure with which user traverse content sections. Among other things, these structures impact the user's journey through content, they determine the number of interactions necessary to reach a target, and ultimately influence how easy or difficult it is to access information. Navigation structure issues become especially critical on mobile devices with limit display area. Moreover, actions such as swiping, scaling, dragging, and tapping that must be perform to execute functions or to navigate may not be apparent to some users and can cause unintentional responses from the interface. For example, when using a mobile device, it is not uncommon for a user to tap or swipe an image intending to see additional detail only to land on a different page or section of the site. The small viewport and minimal cues about interaction functionality often contribute to a less than positive user experience.

Social

Interfaces and associated technologies connect people and resources in unprecedented ways. They enable people to contribute to and participate in the news. People are no longer solely news consumers but contributors as well. CNN.com, for example, has a section of its site devoted to iReports where people can take part in news by uploading compelling and/or urgent stories. People interact by posting comments or participating in discussions with other readers or the author. The interfaces of all major online networks give access to services, such as Twitter and Facebook. By way of a single display, interfaces provided people instantaneous, global access to breaking

newsworthy information. The aforementioned have implications for how content is written, the expectations of journalists to participate in discussions, and the role of citizen journalists.

Standardization

Viewports through which people access news interfaces vary widely, impacting the design of interfaces and how and where people use them. Today, people interact with large devices, small devices, touch screens, keyboards, and devices with extraordinary web browsing capabilities, and those with limited capabilities (Kadlec, 2012). On each device, the visual characteristics and functionality of the digital interface may be distinct, impacting usability and the user's experience with the news. While television monitors and newspapers vary in size, the digital viewports through which people access online news range from large to extremely small. News organizations must adjust the content and content structure dynamically to deliver news to these devices. For instance, in a TV broadcast, the news organization encodes the media according to pre-define standards (e.g., NTSC, Digital-TV) which set, among other things, the dimensions of the content to be displayed. Viewers watch content on displays of various sizes. For newsprint, the organizations use established paper dimensions to format content accordingly. Content delivered on the web gets displayed on viewports of multiple orientations and sizes. Moreover, if organizations adhere to current trends in responsive design whereby the structure and style of content responds to the display, then they must develop sites and applications so that content structure and style respond or are accessible on all types of devices.

Coupled with dynamic content, animation, video, device portability, viewport size and orientation affects how people read and browse news. It impacts how news organizations design interfaces and structure content. Content presented on the 52 inch monitor must be re-designed for a 2.5 inch display.

Scale

Interfaces provide unique indications of scale and amount, compared to more traditional informational sources. Newspaper and television broadcast media clearly delimit the beginning and end of news content. A newspaper represents a certain amount of news coverage for a specific period of time. The number of pages and text density help readers discern the breadth and depth of coverage. Even during 24 hour news broadcasts, viewers can tell where segments begin and end. Coverage of topics is sequential. One topic gets covered before another, with little deviation. Program segmentation, commentary, and commercials help people delineate the amount and range of coverage. For the most part, these same cues are absent in the digital realm. Because digital interfaces offer unprecedented access to content, people, and services, people have almost infinite possibilities to explore news. One might follow a link embedded in a news story, traversing countless news organizations worldwide. Thus, using digital interfaces, it is much more difficult for one to intuit where news coverage begins and ends and the amount of coverage, which likely influences how people read news and how news gets distributed.

Media Convergence

The distribution of multimedia and rendering it within a single interface is an important innovation. It has contributed to media convergence of newsprint and television media blurring the distinctions between traditional newsprint and television-orientated new organizations. "Individuals can watch video on a newspaper site such as *usatoday.com*, or read news articles on television-oriented site such as *CNN.com*, as well as participate in blogs about various topics" (Gibbs, 2008, p. 130). As Opgenhaffen (2011) points out, a convergence of media, technologies, and services has altered how news content is presented and the way people consume it. Convergence has instigated new types

of interfaces that effect communication as well as information access and dissemination. Similarly, mobile devices represent a convergence of services and functionality. Phone, texting, camera, GPS, multimedia entertainment, games, email are integrated in devices and have important implications for how news is obtain and even generated.

At the same time, there is a preponderance of major TV and newspaper websites, each with distinct information and graphical layouts designed to underscore the news organization's television or newsprint tradition and reporting methods. These differences are discernible and can impact how people use sites. Gibbs and Bernas (2009) found greater across-user variability in the viewing of newspaper homepages compared to TV-oriented homepages, which may indicate that TV-oriented sites, with concentrations of links, provide more direct paths to content.

Interaction, Internet of Things and Big Data

Unlike traditional forms of media, today's interfaces are characterized by the potential to collect usage data as a result of a proliferation of connected devices. According to Chang, Dong and Sun (2014), the Internet of Things (IOT) was initially referenced by Kevin Ashton who coupled Radio Frequency Identification (RFID) with the Internet (see Ashton, 2009). The IOT is a network of devices connected to the Internet through RFID technology and other sensing devices that communicate (Chang, Dong & Sun, 2014; Magrassi & Berg, 2002). Potentially every object in the world can be equipped with sensors and connected to the Internet (Fleisch, 2010; Chen, 2013). Rapid and continuous technological development has resulted in computing that is ubiquitous. Computational, sensing and display technologies have become integrated into work and everyday public settings (Valkanova, Jorda, & Vande Moere, 2015, p. 4). Computers are in appliances, offices, vehicles and even being worn by people. Computation and interaction are finding their way in walls, furni-

ture – they are also disappearing, becoming less obtrusive and noticeable. Interfaces and human-computer interactions are virtually inescapable. As the International Telecommunication Union (2005) indicates,

...by embedding short-range mobile transceivers into a wide array of additional gadgets and everyday items, enabling new forms of communication between people and things, and between things themselves. A new dimension has been added to the world of information and communication technologies (ICTs): from anytime any place connectivity for anyone, we will now have connectivity for anything. (p. 2)

The capacity to monitor the interactions people have with devices and to record, often in real-time, the digital traces of those interactions is advantageous (Valkanova, Jorda, & Vande Moere, 2015). Gibbs and Mckendrick, (2015, p. xxiv) citing Goes (2014) indicate, "Analyst, researchers, businesses, and organizations can now inquire about, explain and potentially predict human behavior patterns and trends using data compiled from sensor-equipped devices and the *Internet of Things*." Large amounts of interaction data can be collected and analyzed regardless of the interaction modality, duration, frequency, or the locality in which the event occurred. Moreover, devices that communicate with each other provide for ubiquitous communication and computing, affording a host of context-awareness services (e.g., home automation, environment monitoring) as people move through the environment (Jara et al., 2014).

These enormous amounts of data, commonly referred to as Big Data, are unique because of the *volume* or amount of data that can be accumulated; the *velocity* or real-time analysis that is possible; the *variety* of data, from various devices and sources (e.g., social media, content, behavior) and *veracity* or uncertainty of data due to variation in quality (Chen, Chiang, & Storey, 2012; Waller & Fawcett, 2013; Goes, 2014; Taylor, Schroeder, & Meyer, 2014; Gibbs & McKendrick, 2015). Unlike

other media forms such as newspaper and television, users only have to interact with the digital interfaces and their interactions are recorded – with digital interfaces user actions beget data and make analysis possible. Conversely, to amass data about television viewing habits or newspaper reading habits, the news and information services organization typically must contact news consumers who provide data. Self-reporting about usage behaviors can be problematic since people may be unable to articulate or even understand their own behavior. However, interaction data (behavior) from digital interfaces get recorded as interactions occur providing a clear representation of human-computer interactions.

News and information services organizations use Big Data to analyze behavioral patterns and interaction that can help determine ways to attract users and ultimately how to bring more traffic to a news website. In addition, data analytics can help reveal the type of content that gets the attention of readers and the type of material that retain their attention (Hiers, 2015). Not only are data and analytics used to increase traffic and to direct advertising, increasingly they are used to understand and potentially refine the user experience with digital interfaces and associated content. By tracking interactions, news organizations can make predictions about the type of content someone may find interesting or location data may be used to deliver newsworthy content based on one's location. The possibilities for the IOT, data and analytics are only just beginning to be explored but they have great implications for information services.

Solutions and Recommendations

Examination of interface elements on news websites and applications, suggests, to a degree, a mass production services model, wherein services are viewed as commodities and user and product are separate in production processes. For instance, while engagement at the interface has a role in establishing relations with users, users of major

news sites often encounter unexpected changes to the interface that dramatically affect their loyalty to the site, and how they browse and access to information. Some sites modify the interface without notifying or consulting users, thus separating services (products) and users as well as restricting user input. As Parker and Heapy (2006, p. 28) noted, we are more likely to remember something about the company brand from our interactions with the company than from looking at some element of a design work. It may be that users are more likely to remember the news organization by how the interface supports their interactions and needs. This is particularly germane to online information service interfaces because they serve as the sole enabler of relationships between news consumers and information service providers.

When the interface of a news site changes significantly without notice, rapid innovation and technology trends may be the impetus rather than usability and user experience (UX) design. While many news organizations espouse UX principles, all too often interfaces alter appreciably leaving users surprised and confused. Adherence to UX precepts can likely afford users enhanced experiences at the interface, while at the same time building customer loyalty and commitment to the news organization.

UX design is concerned with the total effect felt by users as they interact with a system, device or product. It encompasses usability and usefulness as well as what the user feels internally (Hartson & Pyla, 2012, p. 19). Several precepts from UX and interface design are germane to the role of today's visually intensive and interactive news interfaces. For example, Davidson, Dove, and Weltz (1999) proposed seven high-level principles to help users formulate accurate mental models of an interface or product (Mathis, 2011): a) simplicity, b) familiarity, c) recognition, d) flexibility, e) feedback, f) safety, g) affordance. Similarly, Shneiderman (2010) provided eight rules of interface design: a) strive for consistency; b) cater to universal usability; c) provide informative feedback; d) design dialogs to yield closure; e) prevent errors; f) permit

easy reversal of actions; g) support internal locus of control; h) reduce short term memory load. As innovations occur and interfaces change, adherence to such UX principles becomes important, especially given that people tend not to engage with multimedia tools and spend limited amounts of time learning new controls or functionally on sites. In this regard, Big Data and analytics can prove useful. Tracking when users abandoned content, or what they clicked or touched or the sentiment of discussions provides valuable data that can help improve the user experience. The IOT and mobile devices enables information service organizations, by way of data, to more fully understand users and their behavior at the interface. These data and corresponding analytics must be used to inform interface design and to ultimately create a better user experience - so that all people can get news and information and be able to comprehend it.

FUTURE RESEARCH DIRECTIONS

Many news organizations today not only provide newsworthy stories but they also attempt to build dynamic communities by establishing connections among sets of information and a diversity of people. These communities or environments and supporting interfaces provide an invaluable source of data about human information-seeking behavior and preferences previously unavailable to news-gathering organizations. At the interface level, organizations are increasingly using innovative digital data collection and analytics to observe and understand trends in order to improve their online practices and the user experience. These data can help organizations monitor and better understand usage patterns, reader attention, interests, and loyalty. Analytics and digital data collection methods will continue to be used to inform decisions regarding news content, interface design, user experience, and news consumption, reporting, and distribution. They will likely pro-

vide additional insights regarding how the design of interfaces and interface elements support or impede users' access to information. User research, analytics and data will play an ever increasing role in online news and information services. There will be continued innovation and greater focus on methodologies for studying online news and information services and how these data can be utilized to refine interface designs and improve services overall.

CONCLUSION

In this chapter, I examined trends in today's news-orientated interfaces and the impact of digital interfaces on news consumption. I discussed how digital interfaces differ from traditional informational sources such as newspapers and television news. I also examined characteristics of today's news interfaces and their implications for how people consume news.

The nature and proliferation of today's interactive multimedia interfaces add complexity, impeding some user access to and comprehension of the news and/or reshaping how people access news. I suggested that UX principles provide a useful framework for examining and building new types of interfaces and that data and analytics can play an increasing important role in this endeavor. All too often it seems that technology innovation, not usability and user experience is the driving impetus for interface design decisions.

KEY TERMS AND DEFINITIONS

Digital Interface: A digital interface is the medium through which humans interact with

computers. Interfaces represent an amalgamation of visual, auditory, and functional components that people see, hear, touch, or talk to as they interact with computers (digital devices).

Human-Computer Interaction and Learning: Refers to interactional processes between learners and computational devices and the extent to which that interaction supports or impedes learning.

Interface: A mechanism that mediates the conversation between a person and a product or system. An interface is a means to make the conversation between the human and machine or product easier.

Interface Design: The process of designing the visual, metaphorical, functional aspects of a product or system. The process of interface design begins with understanding people, the tasks they perform, and the goals they are trying to reach. Based on this information, interface designers create the medium to help users interact with products or systems so they may reach their goals.

Responsive Design: Designing web content in such a way that it responds to any device on which it is viewed. Working from the content structure, designers design websites so when they are viewed on varying sized displays, users can easily access the information content.

Usability: A process of determining how effectively and efficiently people are able to use products or systems created by designers. A core aspect of usability is having people use the product or interface and examine how easy or difficult it is to use. Based on these data, designers make refinements to the system.

User Experience Design: Concerned with the total effect or effects felt by users as they interact with a system, device or product. It encompasses usability and usefulness as well as what the user feels internally (Hartson & Pyla, p. 19, 2012).

Internet Addiction in Context

INTRODUCTION

Internet addiction can be defined as the overuse of the Internet such that it leads to the impairment of an individual's psychological state (both mental and emotional), as well as their scholastic, occupational, and social interactions (Beard & Wolf, 2001). Young (1998) describes Internet addiction as any online-related compulsive behavior that completely dominates the addict's life, interferes with normal living, and causes severe stress to family, friends, loved ones, and one's work environment.

From a historical perspective, in 1996, the American clinical psychologist Kimberley Young (1998) published the results of a two-year study of Internet behavior and misuse, and was the first to place the phenomenon of Internet addiction in a clinical context. This study received widespread public attention, and popular and professional debate. Since the 1990s, Internet addiction has attracted the attention of professionals around the world, mainly from developing and developed countries with widespread Internet access. Some countries, such as the United States, China, South Korea, and Germany, even began developing the first specialized centers focused solely on this phenomenon (Block, 2008). Nevertheless, inconsistencies regarding the terminology still exist. Usually the term "Internet addiction" is used. However, some researches do not agree with using the term "Internet addiction" and use several others, such as "Internet addiction disorder" (Chou, Condron, & Belland, 2005), "compulsive Internet use" (Black, Belsare, & Schlosser, 1999),

"Internet pathological use" (Davis, 2001), "problematic Internet use" (Caplan & High, 2011), and "Internet dependency" (Wang, 2001), each of which reflects a slightly different conception of this behavior. In this text we will use the term "Internet addiction" as an umbrella term for all of these term modifications.

In this chapter, we will first present a short historical overview of the Internet addiction phenomenon and its place in the context of mental health. We will then introduce the contributions of major researchers who focused on defining its core components, designing measurement scales and diagnostic criteria. Furthermore we will focus on the main areas of research in this field: the major surveys regarding prevalence rates and the correlates of Internet addiction. In the last section, we will introduce basic approaches to the treatment of Internet addiction.

The term "Internet addiction" is very broad. It refers to different kinds of overuse of the Internet. Starcevic (2013) stated that the term "Internet addiction" should be abandoned because individuals do not usually get addicted to the Internet in general, but to specific online activities; therefore, being addicted to the Internet implies addiction to a delivery mechanism or to a medium for achieving something. He states that it would be more accurate and appropriate to refer to specific activities that are presumed to be addictive. Some of the most typical online activities related to Internet addiction include online gaming (typically but not only Massive Multiplayer Online Role-Playing Games - MMORPGs), excessive online communication (email, chat rooms, and social

DOI: 10.4018/978-1-5225-2255-3.ch366

networking), cybersex activity overload (visiting online pornographic sites and initiating cybersex relationships), and online gambling (betting via the Internet) (Subrahmanyam & Smahel, 2011). Due to limited space, this chapter does not focus specifically on any of these activities; it focuses on Internet addiction in general.

BACKGROUND

Internet Addiction and Diagnostic Mental Disorder Manuals

A majority of experts include Internet addiction together with pathological gambling, compulsive shopping, sex addiction, and eating disorders in the category of non-substance or behavioral addictions. Behavioral addictions display the basic elements of addictive behavior in relation to certain activities and have similarities with drug addiction, specifically with respect to the genetic (Potenza, 2006), neurobiological (Han, Kim, Lee, & Renshaw, 2012), personal (Potenza, 2006), and clinical characteristics (Grant, Brewer, Potenza, 2006). All of the above-mentioned addictions are included in the diagnostic manuals DSM-5 or the ICD-10 (both are explained in the Key Term and Definitions section), except for compulsive shopping and Internet addiction. Internet addiction was considered for inclusion in the official DSM-5 diagnoses, but, in the end, was left it out. However, Internet gaming disorder (the compulsive playing of online games) is classified in the DSM-5 appendix so as to encourage additional research (APA, 2013). According to Pies (2009), the main reasons against Internet addiction's inclusion in the DSM-5's list of mental disorders are that symptoms of Internet addiction are likely to be the symptoms of other disorders, such as depression or obsessive-compulsive disorders, and that creating a separate category would further expand an already fast-growing list of supposed "disorders" and thus undermine the public's trust in psychiatric

diagnosis. In 2018, the 11th revision of the ICD should be published, but the revision discussion was started in 2012. The ICD-11 Working Group on Obsessive-Compulsive and Related Disorders noted that Internet addiction is a heterogeneous condition, and that use of the Internet may, in fact, constitute a delivery system for various forms of impulse control dysfunctions (e.g., pathological game playing or pornography viewing). In their view, based on the limited current data, it would therefore seem premature to include it in the ICD-11 (Grant et al., 2014).

Diagnostics of Internet Addiction

In the last few years, there have been several proposals for diagnostic criteria for Internet addiction. An absence of a consensus on the nature of Internet addiction has resulted in various authors emphasizing different diagnostic criteria. In most cases, although some researchers have added or removed individual elements, most researchers have adapted the DSM pathological gambling criteria for identifying Internet addiction. The best-known diagnostic criteria of Internet addiction were proposed by Young (1998). To confirm the presence of Internet addiction, five or more of the following points must be present: (1) the person is preoccupied with the Internet, thinks about online activities, or anticipates the next session on the Internet; (2) the person needs to use the Internet for increasing amounts of time in order to achieve satisfaction; (3) the person has made unsuccessful efforts to control, cut back, or stop Internet use; (4) the person is restless, moody, depressed, or irritable when attempting to cut down or end Internet use; (5) the person stays online longer than originally intended; (6) the person has jeopardized or risked the loss of a significant relationship, job, or educational or career opportunity because of Internet use; (7) the person has lied to family members or others to conceal the extent of their involvement with the Internet; and (8) the person uses the Internet

as a way to escape from problems or to relieve a dysphoric mood (e.g., feelings of helplessness, anxiety, and depression).

Griffiths (2000) proposed the following six basic components of Internet addiction, where a high score in all six dimensions suggest that the person is addicted: (a) salience: When the particular online activity turns out to be the most important activity in the person's life and governs their thinking and behavior; (b) mood modification: a subjective experience influenced by the pursued online activity; (c) tolerance: the process whereby increasing amounts of the particular online activity are required to achieve the former effects; (d) withdrawal symptoms: unpleasant feelings, states, and/or physical effects that come about when the specific online activity is discontinued or suddenly limited; (e) conflict: disagreements between the addicts and those around them, or from within the individuals themselves associated with the online activity; and (f) relapse: a tendency for repeated decline into earlier usage patterns of the online activity.

Inspired by the aforementioned core components and diagnostic criteria, experts have constructed various methods for assessing Internet addiction. Available tools can be divided into two categories: scales measuring generalized Internet addiction and scales measuring specific online addictions, especially problematic online gaming, addiction to cybersex, and social networking sites (Weinstein, Feder, Rosenberg, & Dannon, 2014). The above-mentioned first effort to identify Internet addiction was made by Young (1998), who developed a brief diagnostic questionnaire based on the DSM-IV criteria of pathological gambling. There are several tools measuring generalized Internet addiction, such as CIAS - Chen Internet Addiction Scale (Ko, Yen, Chen, Chen, & Yen, 2005) and CIUS - Compulsive Internet Use Scale (Davis, Flett, & Besser, 2002). Different scales were developed for measuring online gaming addiction, like GAS - Game Addiction Scale (Lemmens, Valkenburg, & Peter, 2009) and, for Internet sex addiction, ISST - Internet Sex Screening Test

(Carnes, Green, & Carnes, 2010). Wölfling, Beutel, and Müller (2012) introduced a standardized diagnostic tool for assessing Internet addiction in clinical settings – the Assessment of Internet and Computer Game Addiction - Checklist (AICA-C), which is the only tool that has been tested in a clinical population.

Prevalence Rates of Internet Addiction

Many surveys focusing on the prevalence of Internet addiction have been carried out, resulting in prevalence rates that vary widely from study to study. The problem with these surveys is that various definitions of Internet addiction were employed, different assessment methods and an unambiguous recall period for the presented questions were used, and the number and character of the surveys' participants also differed. In order to determine prevalence, many studies used samples of high school and college students (Cao & Su, 2007; Zhang, Amos, & McDowell, 2008) and some used Internet-based surveys (Wang, 2001; Young, 1998). In studies where representative samples of the general population were selected, the prevalence rates range from 1% in Germany (Rumpf et al., 2014) to 3.4% in the Czech Republic (Šmahel, Vondráčková, Blinka, & Godoy-Etcheverry, 2009).

Regarding the prevalence of Internet addiction across countries in the world, this is a difficult comparison to make due to the different methodology used in individual studies. But it seems that the highest rates are in Asian countries, such as China, South Korea, and Taiwan, where estimates are about 6-15% (Lin, Ko, & Wu, 2011; Ni, Yan, Chen, & Liu, 2009), whereas in Europe and North America, the estimates are lower, specifically 1-5% (Durkee et al., 2012; Šmahel & Blinka, 2012; Villella et al., 2011). Cheng and Li (2014) conducted a meta-analysis of Internet addiction studies in 31 nations across seven world regions and their correlation with quality of life. The highest average prevalence was in the Middle East (studies from

Iran, Israel, Lebanon, and Turkey) with 10.9%. The lowest was in Northern and Western Europe (studies from Austria, Estonia, France, Germany, Ireland, Norway, Sweden, and the United Kingdom) with 2.6%. In this meta-analysis, the average prevalence for Asia (studies from China, Hong Kong, India, South Korea, and Taiwan) was 7.1%. A direct comparison between different studies is impossible, but it seems that the prevalence is higher in Eastern than in Western countries.

Correlates of Internet Addiction

Research shows that Internet addiction is correlated with several biopsychosocial factors and patterns of Internet use. These can be divided into psychopathological factors, personality factors, physiological factors, sociodemographic factors, environmental factors, and patterns of Internet use. The following variables were identified as risk factors for Internet addiction:

1. **Psychopathological Factors:** ADHD, depressive and anxiety disorders, social phobia (Alavi et al., 2012), substance use (Ko, Yen, Yen, Chen, & Chen, 2012), obsessive compulsive symptoms (Jang, Hwang, & Choi, 2008), and conduct behavior (Müller et al., 2015);
2. **Personality Factors:** Low self-esteem (Sariyska et al., 2014), hyperactivity and impulsivity (Wu et al., 2013), high novelty seeking and low reward dependence (Dalbudak et al., 2015), introversion, low conscientiousness, agreeableness, high neuroticism/low emotional stability (Kuss, Shorter, van Rooij, van de Mheen, & Griffiths, 2014), hostility (Alavi et al., 2012), a low level of self-control and self-regulation (Blachnio & Przepiorka, 2015), and low social skills (Caplan & High, 2011);
3. **Physiological Factors:** Stronger blood volume pulse and respiratory response and weaker peripheral temperature (Lu, Wang, &

Huang, 2010), and dysfunctional activation of the supplement motor area for response inhibitions (Chen et al., 2015);

4. **Sociodemographic Factors:** Being male (Ha & Hwang, 2014), family economic disadvantage (Shek & Yu, 2016), low age at initial use of the Internet (Wang et al., 2013), and having divorced parents (Li, Garland, & Howard, 2014);
5. **Environmental Factors:** Loneliness and stress (Alavi et al., 2012), family disharmony (Shek & Yu, 2012), child-parent conflict (Li et al., 2014), affiliation with peers who have lower levels of social acceptance, and youth situated in a class with higher levels of Internet addiction (Zhou & Fang, 2015); and
6. **Patterns of Internet Use:** A high number of hours spent online (Kuss et al., 2013), engagement in different video games (Donati, Chiesi, Ammannato, & Primi, 2015), and excessive weekend Internet use (Xu et al., 2012)

Most of the mentioned factors were researched in isolated studies, which is also a limitation for this knowledge.

Treatment of Internet Addiction

With the increasing popularization of Internet addiction, health professionals have begun to publish treatment approaches for this target group (Orzack, Voluse, Wolf, & Hennen, 2006; van Rooij, Zinn, Schoenmakers, & van de Mheen, 2012; Young, 2007). There is an agreement that the main treatment approach should be psychosocial, especially psychotherapy, which should be supplemented by pharmacotherapy in more serious cases of Internet addiction.

Many psychotherapeutic approaches can be used for the treatment of Internet addiction, as is the case in other mental disorders, and each of them stresses different aspects of the problem.

There are three main treatment approaches:

1. The Cognitive Behavior Approach.

Cognitive behavior therapy sees Internet addiction as a learned way of thinking and behavior which helps the individuals to cope with excessive stress and fulfill their needs. Clients in therapy are encouraged to focus on and identify the thoughts and behavior which lead to the addictive behavior and replace them with adaptive ones (Hall & Parsons, 2001). The treatment programs usually last from two weeks (Koo, Wati, Lee, & Oh, 2011) to three months (van Rooij et al., 2012). The main pioneer of CBT in the treatment of Internet addiction is Young, who formulated her experiences in the treatment model CBT-IA (Young, 2011).

2. The Psychodynamic Approach.

The majority of papers describing the use of the psychodynamic approach on Internet addiction have the character of case studies (Toronto, 2009; Vondráčková, 2011) and, so far, have not proven effective on a large number of clients. The basic assumption of the psychodynamic approach agrees on the fact that addictive behavior serves as compensation or the possibility to escape from/dissociate unpleasant states that the individual experiences in relation to the world (Toronto, 2009). Therefore, the therapist helps the client to become aware, accept, and integrate negative feelings and thoughts connected with these unpleasant states.

3. Family Interventions.

Young (1999) stresses the importance of family interventions, especially when the Internet addiction negatively influences the family relationships. The involvement of family members has two basic goals: the use of family resources and strength to change the addictive behavior and in the decreased influence of the addiction on the family and the individual (Kaufman & Yoshioka, 2004).

The assessment of the quality of the Internet addiction treatment is yet unclear. King, Delfabro, Griffiths, and Gradisar (2011) published a systematic review to assess the clinical trials of Internet addiction treatment and concluded that the current studies have several key limitations in methodology, such as in the diagnosis of Internet addiction, the lack of randomization and the adequate control of comparison groups, and insufficient information about sample and effect sizes.

CONCLUSION

This chapter presented up-to-date studies focused on the diagnostics, prevalence, correlates, and treatments of Internet addiction. We presented several tools for the identification of Internet addiction, although only one of them – AICA-C – was standardized in a clinical setting (Wölfling et al, 2012). The development of more standardized tools is needed for the future. The prevalence rates of Internet addiction were identified in representative studies between 1-3.4% among Western countries and 6-15% among Eastern countries, which is probably still much less than the anecdotal evidence presented by the media.

FUTURE RESEARCH DIRECTIONS

The prevalence studies on representative samples of the population are very rare. We have most of our knowledge about prevalence from adolescents and university students. This is also a goal for future studies. We presented several factors which are correlated with higher Internet addiction: psychopathological, personality, physiological, sociodemographic, environmental, and patterns of Internet use. Most of these factors were revealed in cross-sectional studies which are mostly unable to reveal casual relationships between variables: future studies require research with longitudinal perspectives. We introduced

three basic approaches to the treatment of Internet addiction: the cognitive-behavioral approach, the psychodynamic approach, and family interventions. But the treatment of Internet addiction and its research are both in their infancy and future studies should reveal proven short- and long-term treatment strategies for Internet addicts.

KEY TERMS AND DEFINITIONS

Cybersex: Is a virtual sexual encounter between two or more people connected via the Internet.

Diagnostic and Statistical Manual of Mental Disorders: (DSM) provides a common language and standard criteria for the classification of mental disorders. It is published by the American Psychiatric Association.

International Classification of Diseases: (ICD) is a list of mental and behavioral disorders published by the World Health Organization.

Internet Addiction: Refers to the overuse of the Internet such that it leads to the impairment of an individual's mental or emotional psychological state, as well as their scholastic, occupational, and social interactions (Beard & Wolf, 2001).

Internet Addiction Treatment: Refers to treatment approaches for Internet addiction.

MMORPG: Is the acronym for massive multiplayer online role-playing games, which are online games where a player is able to play with other people all around the world.

Mediated Embodiment in New Communication Technologies

Laura Aymerich-Franch

CNRS-AIST JRL (Joint Robotics Laboratory), AIST, Japan

INTRODUCTION

Becoming someone else in a fantasy or digitally-created world is a daydreaming fantasy often explored in literature and cinema, especially in Cyberpunk. Stories about digital worlds in which characters are transported somewhere else and experience becoming someone new through avatar self-representations -such as in *The Matrix* (1999) or *Avatar* (2009)- create a sort of “meta-transportation” experience to the audience. Viewers are transported into a fantasy world and feel identified with a character which is in turn transported into a new world and transformed into a new character. The possibility of adopting a digital or robotic surrogate body, described in this kind of narratives, is closer to real than ever before thanks to new communication technologies such as virtual reality or last generation robots. As Dyson (2005) argues:

The ‘new’ of new media such as virtual reality, has been identified by its ability to transcend ‘old’ media that are based on seeing (film, television), with a state of immersion based on being. By being in, rather than looking at, virtual environments, the immersant is said to occupy the space and time, the here and now, the virtual present of a separate but ontologically ‘real’ space. In terms of screen culture, the discourse of representation undergoes a strange re-articulation: the ‘as if you are there’ of screen-based media is truncated to a ‘you are there’ – one is in cyberspace, not watching it, one is a navigator, not a viewer (p.86).

Traditional media such as cinema or television and literature are characterized by being passive experiences for the body. *Transportation* in these media is an experience of cognitive, emotional, and imagery involvement into a narrative (Green, Brock, and Kaufman, 2004) that can be best explained from a Cartesian dualistic approach of mind-body distinction. The mind is the true active protagonist in the process of transportation. The mind travels, the body stays. One step further, interactive television, classic videogames, or on-line games, actively involve users in the process of creating or deciding the narrative to increase the feeling of being transported. However, body participation is not a decisive feature in these experiences either.

The principal transformation concerning the experience of transportation in fully immersive systems compared to traditional media is the involvement of the body in the process. In such systems, media interface development is aimed at providing users with fully immersive experiences, with the ultimate goal of making the virtual, real. In these systems, the body plays a central role by becoming progressively embodied in the process. In *the Cyborg’s dilemma*, Biocca (1997) describes this pattern as *progressive embodiment*:

Each progressive step in the development of sensor and display technology moves telecommunication technology towards a tighter coupling of the body to the interface. The body is becoming present in both physical space and cyberspace. The interface is adapting to the body; the body is adapting to the interface (para.2).

DOI: 10.4018/978-1-5225-2255-3.ch367

While *transportation* in traditional media can be connected to Cartesian Dualism, in fully immersive systems, this experience needs to be framed from a body-subject approach (Merleau-Ponty, 1962) or that of embodied cognition (Shapiro, 2010), in which the body is understood as the medium that humans use for having a world (Merleau-Ponty, 1962). For embodied cognition theorists, as in fully immersive systems, embodiment plays a central role in structuring experience and cognition:

To say that cognition is embodied means that it arises from bodily interactions with the world. From this point of view, cognition depends on the kinds of experiences that come from having a body with particular perceptual and motor capacities that are inseparably linked and that together form the matrix within which memory, emotion, language, and all other aspects of life are meshed (Thelen, Schöner, Scheier, & Smith, 2001, p.1).

Body Ownership Illusions

The Rubber Hand Illusion (RHI) paradigm (Botvinick & Cohen, 1998) is considered as the earliest and most relevant precursor of the works on embodiment. On the RHI experiment, participants are seated with their left arm resting on a table. A screen is positioned beside the arm to hide it from the subject's view and a life-sized rubber model of a left hand and arm is placed on the table directly in front of the subject. The subject stays still, looking at the artificial limb. The rubber hand and the real hidden hand are stroked simultaneously with a paintbrush, either synchronously (illusion) or asynchronously (control condition). When stroked synchronously, participants report a feeling of ownership of the rubber hand and mislocalize the position of their real hand towards the fake hand (proprioceptive drift). Visuotactile correlation has been so far the most expanded method to induce the illusion of embodiment of a fake body or body part.

Recently, as an extension of the RHI paradigm, a series of studies have utilized full-body ownership illusions involving fake and virtual bodies in order to explore the mechanisms underlying self-consciousness and, arguably, as a way to demonstrate that the spatial unity between self and body can be disrupted (Ehrsson, 2007; Guterstam & Ehrsson, 2012; Lenggenhager et al., 2007). Specifically, full-body illusions have been used to displace the sense of self-location outside the bodily borders (Ehrsson, 2007; Guterstam & Ehrsson, 2012; Lenggenhager et al., 2007). Other works have looked into how mannequin bodies can be experienced as the own body (Petkova & Ehrsson, 2008) and how the characteristics of the embodied body influence perception (Van der Hoort, Guterstam, & Ehrsson, 2011). Generally, in these experiments, the illusion is achieved by visuo-tactile correlation and a manipulated visual perspective displayed on a head mounted display (HMD).

However, whereas tactile sensory stimulation plays a central role in classical experiments of body ownership transfer (Botvinick & Cohen, 1998), the existing works on mediated embodiment using avatars and humanoids have preferably used other methods to induce embodiment (Alimardani, Nishio, & Ishiguro, 2013; Aymerich-Franch, et al., 2015; González-Franco, et al., 2010; Maselli and Slater, 2013; Nishio, Watanabe, Ogawa, & Ishiguro, 2012; Slater et al., 2010; Watanabe, Nishio, Ogawa, & Ishiguro, 2011), as it will be explained in future sections.

Related Concepts in Media Studies

Self-presence and *Identification* are the most relevant concepts from the Communication Literature related to mediated embodiment. *Self-presence* is used in Virtual Reality to describe the state in which the virtual self is experienced as the actual self (Lee, 2004; Ratan, 2010). The construct of *self-presence* provides a theoretical framework for the study of how users connect to their mediated

self-representations (Aymerich-Franch, Karutz, & Bailenson, 2012). Self-presence, altogether with social and spatial presence, constitute the subdimensions of *Presence*, a broadly studied phenomenon in VR which grew out of the need to understand the effects of highly immersive media technologies (Ratan, 2010). Broadly speaking, *Presence* is understood as the feeling of *being there*, in a mediated environment (Schuemie, Van Der Straaten, Krijn, 2001).

Identification with characters is another widely studied process in the Communication Literature which can be related to embodiment. In studies of media reception, *identification* is described as a mechanism through which audience members adopt the perspective of a character and experience the events that the character goes through as if they were happening to them (Cohen, 2001, 2006). During this process, self-awareness is increasingly lost and temporary replaced with heightened emotional and cognitive connections with the character (Cohen, 2001, p.251). The construct is widely used to study character identification in films and television (Cohen, 2006; Eyal & Rubin, 2003; Hoffner, 1996; Hoffner & Buchanan, 2005; Moyer-Gusée et al., 2011). More recently, it has also been used to study identification in interactive media (Klimmt, Hefner, & Vorderer, 2009; Klimmt, Hefner, Vorderer, Roth, & Blake, 2010; Soto-Sanfiel, Aymerich-Franch, & Ribes, 2010), becoming closer to the concept of mediated embodiment. Most research on identification in media is based on identification with real human or human-looking characters (Cohen, 2006; Eyal & Rubin, 2003; Hoffner, 1996; Hoffner & Buchanan, 2005; Moyer-Gusée, Chung & Jain, 2011; Oatley, 1994). Some works (Aymerich-Franch, 2012) have also used this approach to analyze identification with non-anthropomorphic avatars.

EMBODIMENT IN NEW COMMUNICATION TECHNOLOGIES

Defining Mediated Embodiment

Embodiment is a polysemic word used in a wide range of disciplines, from Philosophy and Psychology to Cognitive Neuroscience and Robotics. Despite its importance in fields such as virtual reality, there have been very few attempts (de Vignemont, 2011; Kilteni, Groten, & Slater, 2012; Longo, et al., 2008) to conceptualize and operationalize the concept. Thus, it remains confusing to the research community what embodiment is on the context of new communication technologies, what its components are, and how it can be measured, studied, and experimentally manipulated.

De Vignemont (2011) distinguishes *embodiment* from *sense of embodiment* in that “embodiment corresponds to a specific type of information processing, whereas the sense of embodiment corresponds to the associated phenomenology” (p.84). In line with de Vignemont’s reflections, Kilteni, Groten, and Slater (2012) define the *sense of embodiment* toward a body as “the sense that emerges when its properties are processed as if they were the properties of one’s own biological body” (Kilteni, Groten, & Slater, 2012, p. 375). Also, for de Vignemont (2011), *embodiment* and *full embodiment* differ in the sense that “E is fully embodied if and only if all its properties are processed in the same way as the properties of one’s body” whereas “for being embodied, there is no need for all the properties of E to be taken into account by the corresponding type of bodily processing, it suffices that some are” (p.87).

Although there is no general agreement, embodiment can be considered to consist of three subcomponents: the sense of body ownership, the sense of self-location, and the sense of agency (Kilteni, Groten, & Slater, 2012; Longo, et al.,

2008). Body-ownership is the sense of owning a body. Self-location is a determinate volume in space in which one feels to be located, normally localized within the bodily boundaries (Blanke & Metzinger, 2009). Finally, agency is “global motor control, including the subjective experience of action, control, intention, motor selection and the conscious experience of will” (Blanke & Metzinger, 2009, p.7). However, more empirical and systematic research is needed to discern the relative contribution of each subcomponent to the overall experience of embodiment as well as to determine whether the three components are necessary conditions to experience the illusion.

To distinguish *embodiment* in the context of Communication Studies from acceptations coming from other disciplines I introduce it as *mediated embodiment*, which can be defined as *the technologically induced illusion of adopting an artificial body in which one perceives to be located*. The concept of *mediated embodiment* has previously been used in a similar manner, to indicate the degree to which the user’s body is connected to the telecommunication system or coupled to the interface (Biocca, 2002).

As the adjective *mediated* indicates, the core differentiation of mediated embodiment to other forms of embodiment resides in that the illusion is created using communication technologies. At the same time, the adjective *mediated* is more inclusive than other possibilities, such as virtual embodiment, because it embraces the experience of embodiment produced by any type of technology, not only virtual reality.

In the current state of the art, the most extended form of mediated embodiment is avatar embodiment in virtual reality. Another form of embodiment is embodiment in a robot. However, the research dealing with embodiment in a robot’s body is still very incipient.

Mechanisms Underlying Mediated Embodiment

H

Clark’s notion of the *negotiable body* is useful to understand why the experience of mediated embodiment is possible. How can an artificial body of an avatar or a robot be experienced as one’s own? Clark (2008) sustains that bodies are open to episodes of transformative restructuring in which new equipment can be incorporated into the thinking and acting systems that humans identify as their minds and bodies (p.31). Such approach may contribute to explain not only embodiment of external objects but also artificial body embodiment in the context of new communication technologies:

Humans are profoundly embodied agents: creatures for whom body, sensing, world, and technology are resources apt for recruitment in ways that yield a permeable and repeatedly reconfigurable agent/world boundary. For the profoundly embodied agent, the world is not something locked away behind the fixed veil of a certain skin-bag, a reasoning engine, and a primary sensory sheath. Rather, it is a resource apt for active recruitment and use, in ways that bring new forms of embodied intelligence into being (Clark, 2013, p.279-80).

At a technological level, in virtual reality, the illusion of adopting a virtual body is achieved by providing sight and sound feedback to the user from the perspective of the avatar using an HMD (Figure 1A). Also, physical movements of users are tracked and synchronized with those of the avatar (Figure 1B) and spaces are rendered according to users’ movements to make interaction possible with the virtual world (Fox, Arena, & Bailenson, 2009). Sometimes, haptic feedback is implemented to improve the sense of embodiment (Stone, 2001). Generally, users are able to see the virtual limbs

of their avatars. In addition, full-body identification with the digital self-representation can be achieved by reflecting the avatar's appearance in mirrors or other surfaces so users gain knowledge of how they look like and are seen by other users in the virtual environment (Aymerich-Franch, Kizilcec, & Bailenson, 2014; González-Franco, Pérez-Marcos, Spanlang, & Slater, 2010).

Full-body embodiment of a humanoid robot (Figure 1C) can be achieved with the use of an HMD to display vision in 1PP from the artificial body and occlude participant's vision from the real world altogether with visuo-movement synchronization of the robot's body (Aymerich-Franch, et al., 2015). With 1PP, users are able to perceive themselves located behind the eyes of the artificial body and within its bodily borders. In turn, body move-

ment makes it possible to discern the embodied body from the surrounding space. However, while the literature dedicated to robot tele-operation is abundant, there are very few works in the domain of robots that focus attention in creating full-body experiences of robotic embodiment. Ishiguro and colleagues induced embodiment of an android arm by providing visual feedback of the arm combined with synchronization of the operator's hand and the robot's hand movement (Nishio et al., 2012, Watanabe et al., 2011). In a different study, they used a brain-computer interface to control the arm (Alimardani, Nishio, & Ishiguro, 2013). In Aymerich-Franch et al. (2015), the illusion of full-humanoid embodiment was achieved by providing first-person audio-visual feedback from the robot using an HMD and a headset, altogether with

Figure 1. Mediated embodiment (ME) process. Users wear a head-mounted display (A), which provides first person audiovisual perspective (1PP) from the artificial body and blocks vision from the real world. Users embody and control an avatar in virtual reality (B) or a robot in a physical environment (C) and experience its body and its surroundings in 1PP. Non-anthropomorphic avatars such as a cube (D), an animal, or an object may also be used for the purposes of embodiment.

robot movement and the reflection of the robot's body on a mirror.

However, multisensory correlations are not always a necessary condition in the creation of embodiment, since 1PP together with the artificial body moving have been shown to be enough to produce the illusion (Aymerich-Franch, et al., 2015). On this regard, while 1PP seems to contribute to the sense of self-location, body movement seems to contribute to the sense of body-ownership (anecdotal observations).

Other factors such as synchronizing gaze direction, head orientation, or body movement between the two bodies as well as providing different sorts of sensory feedback may contribute to increase the feeling of being embodied in both technologies (virtual reality and robots). Also, resemblance of the artificial body to a human body may improve embodiment of the surrogate body in some cases (Tsakiris & Haggard, 2005; Maselli & Slater, 2013). However, the feeling of being embodied can be also obtained in non-human looking surrogate bodies, such as non-human looking humanoid robots (Aymerich-Franch et al., 2015), or even in non-anthropomorphic avatars (Figure 1D), such as three-dimensional geometric shapes (Aymerich-Franch, 2012).

FUTURE RESEARCH DIRECTIONS

Mediated embodiment presents several potential applications. Artificial bodies might be used to explore remote or virtual places and people with mobility impairments might use devices such as brain-computer interfaces to control these artificial bodies and use them as surrogate bodies (Alimardani, Nishi, & Ishiguro, 2013; Tidoni, Gergondet, Kheddar, & Aglioti, 2014). These forms of embodiment are a growing phenomenon thanks to the democratization of virtual reality and humanoid robot technologies, which are now affordable to consumers at individual level.

In view of this expansion, researchers need to act in three directions. First, by finding a more

systematic approach to decompose embodiment that can clearly identify its subcomponents and its relative contribution in the whole experience of embodiment. Second, by elaborating reliable measures specifically designed for mediated embodiment. Measures that are commonly utilized in other forms of embodiment might not always be applicable to embodiment in the context of communication technologies. Finally, and most important, by examining the consequences of mediated embodiment in all the available systems in order to predict them before these technologies expand into the market.

Regarding the latest, it has already been demonstrated that embodying an avatar in virtual reality may cause effects on attitudes and behaviors. Among others, these effects have been analyzed in relation to racial bias (Groom, Bailenson, & Nass, 2009; Peck et al., 2013), prosocial behavior (Rosenberg, Baughman, & Bailenson, 2013), social anxiety (Aymerich-Franch, Karutz, & Bailenson, 2012; Aymerich-Franch, Kizilcec, & Bailenson, 2014), self-objectification (Fox, Bailenson, & Tricase, 2013), or saving behaviors (Hershfield et al., 2011). A particularly interesting phenomenon that identifies the consequences on attitudes and behavior of embodying avatars in virtual reality is *The Proteus Effect*, which describes how the appearance of the embodied avatar is able to modify the behavior of the user. This phenomenon is believed to occur because individuals associate certain traits of an avatar to specific behavioral stereotypes and expectations. Thus, when users believe that others will expect certain behaviors from them because of their avatars' appearance, they engage in those expected behaviors (Yee & Bailenson, 2007). On the other hand, the consequences of robotic embodiment on behavior have not been yet analyzed. Thus, it is important to carefully examine both the dangers and benefits of these effects to promote a positive use and implementation of embodiment technologies. Also, it is necessary to examine whether these effects found for avatar embodiment in virtual reality also occur in robotic embodiment.

CONCLUSION

This chapter introduces the concept of *mediated embodiment*, the technologically induced illusion of owning an artificial body in which one perceives to be located. Mediated embodiment refers to the experience of embodying a surrogate body produced by new communication technologies such as virtual reality or humanoid robots. During these experiences, users may adopt an avatar's body or a robot's body as their own. Most literature on embodiment has either focused on visuo-tactile correlations or movement synchronization to produce the illusion. However, in mediated embodiment, other characteristics such as first person perspective together with the movement of the surrogate body are also able to induce the illusion of embodiment with no need to apply multi-sensory correlations.

Embodiment is not an absolute state which either takes place or not. Users can feel a lower or higher degree of embodiment into an artificial body. When the experience of embodiment in the artificial body is successful, users feel identified with that body. They perceive and interpret the world through it. Users may even conform to the identity of the body they represent and behave accordingly (Yee and Bailenson, 2007).

Given the novelty of the phenomenon, the consequences of mediated embodiment are still unknown. At the moment, avatars in virtual reality and humanoid robots represent the maximum exponents of mediated embodiment. However, as new technologies come out, new forms of embodiment might appear to be included under this umbrella. If, as suggested above, the form of embodiment determines how humans perceive the world and act upon it, mediated embodiment might have important psychological consequences as well as be capable of inducing attitudinal and behavioral changes on the embodied users. These consequences might not at all be insignificant and deserve careful attention from the research community.

KEY TERMS AND DEFINITIONS

Agency: The sense of perceiving oneself as being the cause of the own actions.

Body Ownership: The sense of experiencing a body as the own body.

Embodiment: The illusion of adopting an artificial body as the own body, in which one feels to be located.

Identification (With Characters): The mechanism through which audience members adopt the perspective of a character and experience the events the character goes through as if they were really happening to them.

Mediated Embodiment: The technologically induced illusion of adopting an artificial body in which one perceives to be located, generated with new communication technologies.

Presence: The feeling of really being in an artificial environment.

Self-Location: The place in space in which one feels to be located and which is normally localized inside the physical body.

Self-Presence: A phenomenon taking place in virtual reality by which an avatar is being experienced as if it was the real self.

The Nature of Cyber Bullying Behaviours

Lucy R. Betts

Nottingham Trent University, UK

INTRODUCTION

The continued and rapidly increasing digitalisation of society perpetuates our reliance on technology. There are many benefits associated with our increasing access to, and use of, digital technology and online resources. For example, technology and online resources can be used to: Develop and maintain social connectedness (e.g., Chayko, 2014), promote social responsibility (e.g., Cassidy, Jackson, & Brown., 2009), enhance wellbeing (e.g., Hill, Betts, & Gardner, 2015) and innovation (e.g., Oldham & Da Silva, 2015), prevent cognitive decline (e.g., Slegers, van Boxtel, & Jolles, 2012), facilitate knowledge acquisition (e.g., Thorpe et al., 2015) and knowledge transfer (e.g., Erickson & Johnson, 2011), and complete day-to-day activities such as monitoring health behaviours (e.g., Banchs, & Scher, 2015). However, this increasing access to, and reliance on, technology is not without risks. One such risk is that technology can be used as a mechanism to engage in antisocial behaviour directed towards specific others. For example, through threatening emails and images, and spreading rumours technology can be used to intimidate and victimize others (Dehue, 2013).

Cyber bullying represents a specific form of aggressive behaviour directed towards an individual that takes place using digital means (Law, Shapka, Hymel, Olson, & Waterhouse, 2012). Cyber victimisation can be considered as the experiences of being the target of bullying behaviours. The current chapter will begin by exploring what acts constitute cyber bullying and the various forms that cyber bullying behaviour can take. The chapter will also explore why in-

dividuals engage in such behaviour. Finally, the chapter will make some recommendations that should be considered by researchers examining cyber bullying.

BACKGROUND

Interest in understanding victimisation experiences and bullying behaviours was initially prompted by Olweus' work in the 1970s and subsequently by the wealth of research evidence that has reported longitudinal relationships between experiences of bullying and wellbeing and adjustment (e.g., Fergusson, Boden, & Horwood, 2014; Ttofi, Bowes, Farrington, & Lösel, 2014; Wolke, Copeland, Angold, & Costello, 2013). Together, these studies have suggested that negative consequences may occur for those individuals who engage in bullying behaviour and those who experience victimisation.

Cyberbullying involves individuals using technology as a medium to bully others (Smith, 2009) and has been defined as "the use of the Internet or other digital communication devices to insult or threaten someone" (Juvonen & Gross, 2008, p. 498). Following a recent review and meta-analysis of existing cyber bullying literature, cyber bullying was defined as: "(a) intentional aggressive behaviour that is (b) carried out repeatedly, (c) occurs between a perpetrator and victim who are unequal in power, and (d) occurs through electronic technologies" (Kowalski, Giumetti, Schroeder, & Lattanner, 2014, p. 37). Understanding young people experiences of cyber bullying is important because it has been regarded as an "emerging international public health concern" (Nixon, 2014, p154).

DOI: 10.4018/978-1-5225-2255-3.ch368

FORMS OF CYBER BULLYING

Cyber bullying can occur in many forms and the variation, to some extent, represents the evolving nature of technology. Consequently, there is often little agreement among researchers, practitioners, and young people as to what constitutes cyber bullying. Some researchers, such as Mason (2008), have suggested that cyber bullying comprises both written and verbal acts which can be aligned to the more traditional face-to-face forms of bullying. Conversely, other researchers such as Tokunaga (2010) suggested that cyber bullying includes elements of aggressive, hostile, and harmful acts that are carried out through an electronic device. However, whilst different conceptualisations of cyber bullying have been proposed, when assessing cyber bullying behaviours and cyber victimisation experiences it is important to consider: (a) what technology individuals actually use and (b) how individuals use the technology. Therefore, it is likely that as new technologies emerge and current technologies evolve, new forms of cyber bullying will also continue to emerge and evolve (Slonje, Smith, & Frisé, 2013).

Parallels have also been drawn between cyber bullying and the various forms of face-to-face bullying. Mark and Ratliffe (2011) argued that cyber bullying is a form of relational bullying that uses technology, rather than face-to-face methods, as the medium to bully others. For example, technology can be used to victimise by calling others names, making threats, spreading rumours, disclosing another individual's private information, and purposefully socially isolating or excluding individuals. Similarly, Wang, Iannotti, and Luk (2012) argued that parallels could be drawn between face-to-face relational bullying and cyber bullying as both forms of bullying involve verbal bullying, social exclusion, and spreading rumours but not physical acts, although of course the medium through which these acts occur is different. However, whilst parallels have been drawn by some researchers between face-to-face bullying and cyber bullying it is clear that some

young people regard them as distinct entities. In addition to young people's perception that cyber bullying is distinct from face-to-face bullying, further evidence of this distinction is provided by research that has reported that the different forms of bullying have distinct consequences (e.g., Kubiszewski, Fontaine, Potard, & Auzoult, 2015; Pieschl, Kuhlmann, & Prosch, 2015). Some young people also regard cyber bullying as a distinct form of bullying that is perceived to be more serious than face-to-face bullying (Mishna, Saini, & Solomon, 2009). One potential explanation for why young people regard cyber bullying as more serious than face-to-face bullying is that whilst cyber bullying may occur because of something that happened at school (Cassidy et al., 2009), the accessibility of technology means that incidences of cyber bullying often extend beyond the school day. Consequently, compared to face-to-face forms of bullying, cyber bullying is regarded as more relentless in nature because the constant connectiveness of society means that it is harder for the target to avoid cyber bullying and, as such, the negative consequences are likely exacerbated (Davies, Randall, Ambrose, & Orand, 2014).

There is also little agreement amongst researchers as to whether cyber bullying represents an indirect or direct form of bullying. For example, Huang and Chou (2010) argue that because of the range and scope of technology available cyber bullying can be regarded as an indirect form of bullying. Conversely, Vandebosch and van Cleemput (2009) argue that cyber bullying comprises both direct and indirect forms. The direct forms of cyber bullying include physical (e.g., purposely sending a virus infected file), verbal (e.g., using the internet or mobile phone to insult or threaten), non-verbal (e.g., sending threatening or obscene pictures or illustrations), and social (e.g., excluding someone from a group online) acts. The indirect forms of cyber bullying can involve disclosing entrusted or private information (e.g., through an email), masquerading (e.g., deceiving someone by impersonating someone else), spreading gossip (e.g., using a mobile phone, email, or chat

facility), and taking part in voting on a defamatory polling website. In addition to the forms of cyber bullying outlined by Vandebosch and van Cleemput (2009), Calvete, Orue, Estévez, Villardón, and Padilla (2010) suggested a number of additional acts that constitute cyber bullying. In particular, intentional exclusion from an online group; spreading, rumours, gossip, or embarrassing comments about an individual on the internet; circulating the link of such comments on to others; hacking an individual's email account in order to send messages that would cause trouble for the victim; and filming someone whilst they were forced to do something humiliating or whilst they are being attacked.

Alongside the previously mentioned forms of cyber bullying, the use of images as a form of cyber bullying is increasing with webcams increasingly being used as a mechanism to victimise others. Mishna et al. (2009) reported that many of their participants regarded webcams as an integral part of cyber victimisation. In particular, participants reported that they were blackmailed in to performing various acts in front of webcams to prevent the bully from disclosing personal information about them. Similarly, Blakeney (2012) suggested that images could be used to victimise both in the form of inclusion where a hurtful or harmful image was sent directly to the victim or exclusion where a harmful image about the victim was sent to others, often without the victim's knowledge. Aligned to the issues around blackmail and image manipulation, cyber bullying can also comprise identity theft. In some cases of identity theft, the bully may purposefully adopt the identity of one of the victims' friends before carrying out the bullying episode to heighten the sense of fear in the victim (Mishna et al., 2009).

More recently, Chisholm (2014) proposed 11 behavioural acts that could be regarded as cyber bullying: (1) catfishing (i.e., tricking people to relationships by creating false profiles), (2) cheating, forming roving gangs, and blocking entry points in games, (3) spreading insults, images, or humiliating or threatening messages, (4)

flaming (i.e., adopting an argumentative style), (5) impersonating others, (6) slamming, (7) rating (i.e., taking over a device without the target's knowledge), (8) relational aggression, (9) sexting, (10) shock trolling (i.e., creating offensive posts to get a reaction from other users), and (11) stalking or threatening violence.

Together, there are various forms that cyber bullying can take which can encompass both direct and indirect means. However, the media through which these bullying episodes occur can also vary. For example, Beale and Hall (2007) suggested that cyber bullying can occur through: Instant messenger, social networking sites, email, small text messaging, websites, voting booths, chat rooms, and bash boards. It is likely that many of the forms of cyber bullying previously outlined in this chapter can take place through multiple means of technology. Consequently, the range of media that can be used to cyber bully has led to some arguing that researchers should examine both the content of the bullying episode and the media through which it occurred (e.g., Akbulut, Sahin, & Eristi, 2010).

Whilst much of the literature has focused on the use of online media to engage in bullying behaviours, both the increasing use of mobile telephones and the increasing functionality of many mobile telephones and smart telephones, means that such devices can also be used during cyber bullying episodes. For example, children report experiencing hurtful small text messages as a form of cyber victimisation (D'Antona, Kevorkian, & Russom, 2010; Marsh, McGee, Nada-Raja, & Williams, 2010). Although some researchers have argued that cyber bullying using mobile phones was distinct from cyber bullying using personal computers (e.g., Slonje & Smith, 2008; Wang, Iannotti, & Nansel, 2009), more recently Slonje et al. (2013) argued that the changing capabilities of smart telephones means that cyber bullying using mobile telephones and online devices are beginning to merge. Consequently, it is important to examine both the media used to cyber bully and also the content of the bullying episode.

Although cyber bullying can take many forms as discussed in the chapter, what young people experience may differ. For example, the most frequent forms of cyber bullying young people from Spain reported experiencing were: stealing passwords, frightening telephone calls, offensive or insulting messages, and slandering (Garaigordobil, 2015). Therefore, researchers and practitioners should examine the various forms of cyber bullying when examining the influence of cyber bullying as it may be that the different value attached to these various episodes may determine the psychological consequences for the individual.

FUTURE RESEARCH DIRECTIONS

One pertinent point with regard to the many definitions and characteristics of cyber bullying, is how those who experience cyber victimisation view the behaviour directed towards them. Specifically, some individuals who experience cyber victimisation may misinterpret the intended motives behind the behaviour as teasing and, as such, may not consider it cyberbullying (Dehue, Bolman, & Völlink, 2008). Moreover, behaviour that others regard as cyber bullying may not be interpreted as such because of the norms of the peer group that an individual belongs to (Dehue et al., 2008). In other words, such behaviour whilst meeting the definition of cyber bullying, may be regarded as normative and acceptable behaviour within the group. Together, these variations in how behaviour is interpreted may result in variations in the prevalence rates of cyber bullying. Consequently, researchers such as Hopkins, Taylor, Bowen, and Wood (2013) have argued that it is important that researchers and participants develop a shared understanding of the definition of cyber bullying behaviours and cyber victimisation experiences before data collection commences. However, it is important to acknowledge that young people may be relying on existing or taught knowledge when discussing cyber bullying (Pieschl et al., 2015) which may be different from the researchers' understanding.

The previous studies discussed in this chapter have highlighted a range of forms that cyber bullying can take and these are generally conceptualised as unwanted behaviours directed towards an individual or their friends (Akbulut et al., 2010). However, according to Akbulut et al. the extent to which an individual feels that they are a specific target of these unwanted behaviours is one mechanism for distinguishing between cyber victimisation and more general encounters in the digital environment. For example, encountering obscene images in web pages, obscene pop ups, spam, or propaganda were regarded as not constituting cyber victimisation because participants felt that these were not personally targeted towards them. Conversely, when these same images and messages were encountered through instant messenger systems, participants regarded them as cyber bullying because they were directly targeted at the individual. Therefore, in future studies researchers may need to recognise the content of the messages and also the media through which they are received as there appears to be context dependent aspects that lead to behaviour being interpreted as cyber bullying behaviours and cyber victimisation experiences. In support of this proposition Calvete et al. (2010) argue that when examining cyber bullying and cyber victimisation researchers and practitioners should consider both the content of the bullying episode and the modality used.

As previously noted how we engage with technology is changing and as more technology becomes available it is important that the conceptualisations of cyber bullying behaviour and cyber victimisation experiences continue to be refined by researchers and practitioners to reflect this. Moreover, by refining the definition and conceptualisation of cyber bullying it will ensure that as the new forms of cyber bullying emerge with the technology (Slonje et al., 2013) researchers are able to accurately assess individuals' cyber victimisation experiences. Therefore, researchers should consider adopting a bottom-up approach when devising definitions of cyber bullying behaviour

and cyber victimisation experiences so that they fully capture the participants' experiences and examine a range of behaviour across the media that young people report using as Mehari, Farrell, and Le (2014) advocate.

CONCLUSION

Whilst cyber bullying represents a relatively new phenomenon, there is an emerging line of research that has tried to assess individuals' experiences both from the bullying behaviours they engage in and their victimisation experiences. From this research it is clear that whilst cyber bullying can occur through a range of medium and take many forms, it is important to recognise that how the victims interpret the intent behind the episode depends on whether they regard it to be cyber victimisation. Further, the wide range of media that are used to victimise others and the evolving nature of technology should be taken in to consideration when researchers and practitioners examine cyber bullying to ensure that the measures are as accurate as possible. There is also emerging evidence of how cyber bullying differs from more traditional forms of bullying and again this is something that should be acknowledged by researchers and practitioners.

KEY TERMS AND DEFINITIONS

Bash Boards: An online bulletin board or chat room where users can anonymously post messages.

Bullying: A series of aggressive acts directed towards an individual who is often weaker in some way than the person carrying out the act. The aggressive acts can take many forms.

Cyber Bully: An individual who uses technology to carry out acts of bullying.

Cyber Bullying: An act of bullying that can take many forms but involves the use of technology.

Direct Bullying: Involves an act of bullying that the victims is aware of and can be observed.

Indirect Bullying: Involves isolating the victim of bullying from their social world and often occurs without their knowledge.

Psychosocial Adjustment: A reflection of an individual's psychological wellbeing that is influenced by their experiences in the social arena.

Victim: An individual who the acts of bullying are directed towards.

Victimisation: The experience of receiving acts of bullying.

Screen Culture

Ana Melro

University of Aveiro, Portugal

Lídia Oliveira

University of Aveiro, Portugal

INTRODUCTION

Technology and media usage cannot be separated from screens. Examples such as television, computer, smartphone, mobile phone, tablet, e-book reader, multimedia player (music and / or audio), camera and camcorder, watch, digital advertising public panels, virtual reality glasses. In fact, if the goal is to understand what can be considered as a screen, the examples will not cease to increase.

The major goal of the article is to explore the screen definition and the way in which it has emerged in society, in a cross way, almost without being noticed, but ubiquitously, even becoming inseparable from most of the necessary activities. Thus, after almost 20 years of Levinson's (1998 [1997]) reflection and analysis on the need to define a screen taxonomy, it is increasingly relevant to reflect on the screens' nature and on their effects in individuals' daily life. So, how did media and screens step into peoples' lives in such a way a new culture was created and disseminated?

Despite true ontological differences between the artifacts that incorporate screens, there is a progressive process of dilution of the specificities, with the convergence of functionalities and contents. The television becomes interactive and its consumption is increasingly customizable and individualized; the computer and mobile devices allow access to television. One uses the computer to make phone and video calls. The screen as a unifying feature turns out to be the visible side of an ongoing process of convergence that in the

short term will be felt more systematically in the consumption and sociability logics.

This has a lot of implications in all sort of societal levels. In the political sector (e-governance, active citizenship in political decisions); economic sector (new ways of communication and business structures) and cultural sector (e-museums). But also at a micro level, with the need to reorganize familial, labor, scholar and leisure processes around media.

Nowadays, technology is perceived as extension of man (McLuhan (2008 [1964], p. 82). By recognizing the change enhanced by media one can also recognize the effect in the new medium (Federman, 2004, p. 2). The way the above mentioned societal practices changed are intimately related to the way media (and the perceptions of media) also suffered transformations.

A screen culture arises (Chambat & Ehrenberg, 1988), accepted by individuals as a second culture. Media are included in individuals' lives as a second skin, because they are sensitive, ubiquitous and transparent.

Society had suffered major changes and mutations, in order to include media. People comprise media and use them for him/her best purpose. Cyber and screen culture are becoming the focus of social relations of all types (familial, labor and leisure). These were the justifications for the importance of this reflection regarding screen culture.

The article aims to present a state of the art around screen and media uses, their existence and transparency and provide a definition of the concept.

BACKGROUND

Screen Culture: State of the Art

Considering the importance of screens in individuals' daily lives, it is pertinent to draw a chronological path of the main authors that have addressed the topic of screens and were interested in defining the artifacts that usually arise coupled.

Back in the twentieth century, Lev Manovich (1995), when defining what can be considered a screen, noted that screen characteristics can be attributed to a computer monitor, but also to something more unique, such as a painting or a play. Thus, the screen is the frame that separates two different spaces that coexist in some way (Manovich, 1995, p. 1). This will be the screen definition used here, and for the purpose of this article, screen always appears associated with a technological artifact (television, computer or mobile phone). For Manovich (1995), this screen is not neutral. Instead, it has an aggressive status, *"It functions to filter, to screen out, to take over, rendering nonexistent whatever is outside the frame."* (Manovich, 1995, p. 2). Thus and complementing the previous idea with Nelson Zalago's (2010) notion of screen (2010), this is the boundary between the device and the individual receiving the transmitted content (Zagalo, 2010, p. 35).

For an analysis of the differences between the screens studied here, the prospect of Levinson (1998 [1997]) is a starting point. When the author addresses the issue of the twentieth century screens, he warns of the differences in their nature, in particular between the television and the computer, and in this context it shows the need for a taxonomy of screens (Levinson, 1998 [1997] pp. 199-211).

Although radio, photocopying, electronic publishing and fax, the twentieth century can indeed be characterized as the century of the screen. It was so from the beginning. [...] We know our culture, both produced things to the screen, as it was substantially shaped by them. We also know

that the screens are not monolithic in its cultural importance and that different types of things are broadcasted by different types of screens and involve different types of cognitive and emotional processes. Our question, then, is what kinds of things appear in what kind of screens - especially computer screens - and for what purpose. To find an answer, to start building a taxonomy of screens [...] (Levinson, 1998 [1997], p. 199).

Adriana de Souza e Silva (2006) carried her study on the use of social interfaces (designated screens under the definition of the present article) in mediating the relationship between two or more individuals, or in the context of social relations established online. For the author, those interfaces redefine either the communication or the space in which these relationships occur (Silva, 2006, pp. 261-262).

In this perspective, screens are not the only artifacts considered, but, above all, spaces and spaces' convergence, which is something associated to screen usage. This convergence and the emergence of a new space is designed by the author as a hybrid space where the physical and digital converge, but more than that, they are mobile spaces, carried by users in their portable devices, once they are connected to the internet and to other users (Silva, 2006, p. 262).

Screens are, therefore (and increasingly so) a medium, a way of mingle in the real world, with this being referred by Introna and Ilharco (2006) as a "screened world" (Introna & Ilharco, 2006, p. 58). For these authors, the screen is not so much what it represents by itself, but what it transmits to the individual, the message, the content that appears represented on the screen, whether text, images, colors, graphics, etc. (Introna & Ilharco, 2006, p. 62). This way, the user relationship with screens is highly focused on the content and context and not so much on the physical artifact. For that reason, expectations placed on screens are very contextual, and linked to its place in a particular context. For example, at a cinema it is expected that video and image are transmitted, whereas

when opening email it is expected that messages are showed. Screens capture the individual's attention and hold it in the various social contexts (work, leisure, family), but they also make the individual's place in the world clear and show him/her how to be in this world. We look at screens, and we find our way of being in the world (Introna & Ilharco, 2006, pp. 65-66).

Murolo's perspective (2010) follows the direction of screens' unification in media convergence. For the author, the individual is confronted with new screens, new because there is a connection between image and languages which allow for a meaningful construction. New languages, such as photography, animation, audiovisual and multimedia, converge in screens. Quite often these languages' confluence with screens is a bit controversial, in the sense that it tries to embody new meanings in old artifacts, when new artifacts (or new screens) already demand a specific identity (Murolo, 2010, p. 2).

These screens are ubiquitous, including themselves (sometimes meddling) in individuals' social practices "in a usual, confusing and contradictory way." (Murolo 2011, p. 41).

New media and screens attached to it are invisible and define individuals' life through that invisibility, mostly when people stop to think of screens' existence and assume an omnipresence, except when a problem that needs to be solved occurs and gain their visibility state again (Deuze, 2012, p. 111).

It is possible to discuss if this is the spectacle or simulation society, but one cannot not immediately conclude that this is a screens' society, in part because a screen is the frame that divides two different but coexisting spaces (Manovich, 1995, p. 1). Lipovetsky (2010) considers that this society is a screensphere, living in a widespread screen state, with screens anywhere and time, whether at shops, airports, restaurants, bars, subway, cars and planes, of various sizes, textures (smooth, big, miniature, mobile, tactile, graphic, video) and with different capabilities (information, surveillance, entertainment, atmosphere),

imposing a screenocracy where everything is a screen (Lipovetsky, 2010, pp. 10 and 21-22), a new screenculture where transparency is a requirement, involvement and immersion (Zagalo, 2010, p. 51). But it is also demanded a sensuality that promotes an almost intimate relationship between screens and their users, verified by the dissemination of tactile screens all over the places and technological artifacts.

According to Pinto (2005), Lipovetsky (2010), Rivoltella (2010) and Frau-Meigs (2011) we live in a screen society, we are screen individuals.

Divina Frau-Meigs (2011) believes that screens "are the center of all the connection system, as entertainment and services providers. [...]. The screen is present in all spaces, at all times". (Frau-Meigs, 2011, p. 72).

Screens are the intermediaries of individuals' uses of media. Because of that, media assume an epidemic feature, resulting in the creation of a relation of intimacy, seduction and second skin.

Thus, this state of the art will be finished with Cardoso and Quintanilha (2013), regarding the possibility of a sociology of mediation and screen. The authors say "that the focus on the study of the mediation processes and screens role is now divided between three spatial dimensions of social relations frame: the house, the work and intermediate spaces between those. In all three, mediation takes place on the screens we choose to hold or those who accompany us in our pockets, bags or briefcases." (2013, p. 17). Having, therefore, the screen a central role in social, temporal and spatial mediations.

Screen: A Definition Proposal

The screen definition can be quite ambiguous. For example, shadow plays, famous in Eastern archaic societies, were a form of storytelling with moving images in two dimensions, projected continuously on a screen. It was probably the first time that a canvas was used to visualize images and where the utility it could have for theatre plays was apparent. Figure 1 shows this: a canvas is a screen.

Figure 1. Shadow theatre

Source: Moving Image Museum, Portugal

Dating from the eighteenth century, optical boxes served to peek “views”, prints of cities or handmade colorful landscapes. They are designated “Brave New World” because of the fantastic images they gave access to. A box is a screen.

But there are other examples, such as a dark camera where one could see images (Figure 3); a mirror and a light used for images projection on a canvas (Figure 4), in this example the canvas and

Figure 2. Optical box

Source: Moving Image Museum, Portugal

Figure 3. Dark camera

Source: Moving Image Museum, Portugal

the mirror are screens; or a wall used for image projection is also a screen (Figure 5).

In recent years, it a bigger interaction with the screen and the broadcasted content has been possible, mostly through touch; in more influential ways, such as sending messages (SMS or phone keypad...) to affect what is seen; or even in a social perspective, the messages exchange in chat rooms with others who are watching the same program, for example.

The screen has acquired essential features for its use, such as familiarity, with people integrating new media in their daily lives in such a way that renders screens quite usual and familiar, as opposed to a foreign object. Through familiarity screens also become transparent, being used without their presence noticed. In addition, displays are increasingly touchable and therefore sensitive, i.e., there is no longer such a visible distance between the individual and the screen that conveys him/her to other worlds, they (screens and individuals) are closer to each other; the screen was developed to

Figure 4. Image projection through reflex

Figure 5. Image projection to a wall

Source: Moving Image Museum, Portugal

allow an approximation of its user physical touch, while increasing the link between devices and the individual. Finally, the screen is the nearest supplier of the information sought and/or found, replacing, in many cases, the mouse and the keyboard, serving as the direct interface between information and individual.

Thus, the article calls upon various definitions to present one of what is a screen within the Screen Culture presented here. The Dictionary of Media and Communications defines this concept as a flat surface on which images are projected (Danesi, 2009, p. 262), and Manovich (1995) complements this definition by stating that it is “a flat, rectangular surface positioned at some distance from your eyes” (Manovich, 1995, p. 1). However, these perspectives are quite reductive of what it is intended to analyze here.

The screen has four essential functions: it is a mediator (between physical and virtual life), a sensations promoter (provides emotions of all kinds when communicating a certain content), a world performer (it plays all the content asked) and a worldviews creator (provides different perspectives of all subjects). You cannot think about media consumption off screens, and this aspect has been thought by the great mass media, to the extent that, increasingly, all have an Internet presence, from radio to the press and are available in all various screens.

Our screen definition proposal is that this is the ontological somatization of mediation. The screen is what allows the message to be transmitted to the individual, that is, the computer, television and mobile phone monitors. It is something more physical and sensory than virtual. Screens are the connection between the individual and the other side, being the other side what he/she is looking for (or, if not looking for, will eventually going to find), another world and another action.

Media and Screens Appropriation

Relevant to the comprehension of Screen Culture is the understanding of media and screens appropriation. Not only the media is present in the primary socialization, it also became part of people's lives over the years in various contexts (Aroldi & Colombo, 2007, p. 39), i.e. firstly, screens impose their presence to the individual, but later the individuals are the one imposing their presence to the screens (and even contribution to their mutations). The parallel view is the (non-) integration of certain artifacts and tools at a later stage of an individual's life (secondary socialization), in which the familiarity with the media is not as high, but rather a challenge that has to be accepted if you they do not want to be late at

Figure 6. Process of social definition of a new communication technology (or medium)

Source: Aroldi & Colombo, 2007, p. 40

the evolution of the instruments at their disposal (Aroldi & Colombo, 2007, p. 39).

But then, how is a new technology incorporated (e.g., when referring to individuals belonging to the 1950's generation)? Which path is followed to get to the frequent use and unconscious level? Aroldi and Colombo (2007) propose the process of social definition of a new technology. The authors suggest a way in which the approximation of different generations to media is done, considering, on one hand, the technology itself, belonging to a particular generation (being important the era when the technology came about) and, on the other hand, the representation and use of this technology by certain generations (Aroldi & Colombo, 2007, p. 40).

According to the authors, the incorporation occurs in certain social identities, such as generational; but it is also reflected in technologies and social discourses, which, overall, is reflected in a new social setting, since it is an important part of the socialization process, changing even its structures and its symbolic value (Aroldi & Colombo, 2007, p. 40). In fact, following this line of thought, Sáez Vacas (2011) proposes a model of human evolution over time, taking into account the "intelligence-system". According to

the author, the evolution is carried through certain tools: the environment, the hand, the brain, intelligence and, finally, the technology, which, in turn, uses all of the tools mentioned above. Thus, individuals crossed the primate state to achieve *Homo habilis*, and are now in the state of *Homo digitalis* (Sáez Vacas, 2011, p. 8).

Similar to Sáez Vacas (2011), Ilharco's theory (2007) considers that the individual has been naturally learning how to be in the world, which consequently prepares him/her for how to use technologies that he/she will find, such as mobile phones, computers, televisions, cars or others. Thus, the user will understand media, and when he/she understands the mobile phone, for example, he/she also knows what it means and how to make mobile phone calls. In fact, the author claims that all these artifacts are things taken before being knowable things (Ilharco, 2007, p. 62).

Continuing with Ilharco (2007), and following the thought of Heidegger (1977), in this natural apprehension and appropriation of new media, individuals are shown as part of an efficient orderly process, called *Ge-stell* (or "Enframing") (Heidegger, 1977, p. 19). With the increasing number of technology to be integrated into the daily lives of individuals, the *Ge-stell* arises, "the framed is

Figure 7. Human evolution

Source: Sáez Vacas, 2011, p. 8

re-framed” as a painting within another painting (Ilharco, 2007, p. 66). The broader frame of users’ life appears re-framed in the artefacts, with the internet occupying an increasingly importance.

Thus, it is perceptible that as individuals appropriate media and screens, the more familiar they become with them, assuming a characteristic of continuity between the hands, fingers, brains and technology artifact/screen.

FUTURE RESEARCH DIRECTIONS

Considering the ubiquitous spread of screens, the research perspectives in this field are manifold, from the technological scope of screens as physical artifacts, where the challenge is to create flexible displays that can be wound as a sheet of paper with surfaces easy to read in contexts of high brightness, to the screen as a socio-technical space of social interaction. In this sense, research is challenged by the issue of transmedia narratives of media convergence that finds in the screens the ability to manifest itself. This area encompasses literature, audiovisual, screenwriting and information visualization from big data analysis.

The issue of social temporalities changing with the use of new media was another topic that should be further analyzed. Above all, it should

be understood whether individuals are prepared for those new temporalities and spatialities, or whether individuals’ temporalities are changing and how they have adapted, which could be studied through a longitudinal study.

The safety topic in the use of new media is already of interest to many researchers, especially those that are government-oriented that enable developing ways of a conscious media use. It would be interesting to research this topic through concrete applied measures, especially in rural areas, which are often overlooked by public policies.

It would also be interesting to study the screen as a space of self-projection, namely how new generations build their identities and their self-concept through what is projected of themselves on screen.

Finally, it is also recommended the study of the Screen Culture in the Internet of Things (IoT) context, so as to understand how this new trend gives rise to more and more individuals that are hyperconnected.

CONCLUSION

With the objective of completing some of the ideas discussed here, we return to Sáez Vacas (2011) and verify that there is not a total lack of

technological artifacts in the individuals' daily lives, although the preferred use falls within the computer- internet, mobile phone or television. Currently, screens are more and more touchable, and therefore pervasive screens. So if, according to the author, *Homo digitalis* is characterized by the use of a brain prosthesis, being this the keyboard, the mouse and the screens of all devices, this prosthesis has mutated since the keyboard and mouse were replaced by the screen and the touch,. Then, the emergence of *Homo Digitalis sensitu* can be assumed, for whom the sensations transmitted through contact with the devices and the proximity that unconsciously is created with these devices is increasingly important.

Deuze (2012) suggests that the impact is so profound and overwhelming that one can no longer consider the media as the extension of the man (as did McLuhan (2008 [1964])), because they are no longer external to him/her, so a comparison between media and life is not possible because "we are the media." (Deuze, 2012, pp. 65-66). The screen's growing invisibility and ubiquity has contributed to this purpose, so the focus is now on the task (and eventually the skills required for it performance) and not the tool itself (Weiser, 1994, p. 7). Weiser even compares technology to children, in the sense that both must always be present, are the invisible creations, taken for granted, carried effortlessly throughout life (Weiser, 1994, p. 8). This appropriation is also performed with screens, connective instruments to the content, as stated by Coelho and Neves (2010) "In a lot of what we do and what is done to us, what we perceive and what we think, we can hardly be separated from screens and their perceptual experience" (Coelho & Neves, 2010, p. 102).

New media and screens are the excellence mediators between presence and virtual life, in a logic of social reproduction in both worlds. They are mediating social knowledge and consumption activities, facilitating their appropriation and domestication (Silverstone, Hirsch & Morley, 1992, p. 44). This is something that can be perceived as negative, and this issue should undergo further study, perhaps a longitudinal study over the years

that allows for the understanding of the true effects of technology in individuals' lives.

One of the conclusions is the screen transparency evidence, with the naturalness with which they mingle in the individuals' lives, so that the activities for which it is necessary to use new media are already carried out without individuals being aware of its presence, and this is an essential feature of the development and massification of any new technology, as claimed by Weiser in 1991: "the most profound technologies are those that disappear. They weave themselves into the fabric of everyday life until they are indistinguishable from it." (Weiser, 1991, p. 3). In the opinion of Furtado (2007), we are witnessing the change of the book medium to the screen medium, which brings changes to the relationship between Man, cognition/impairment, culture and body with the world (Furtado, 2007, pp. 106- 107).

We live in a time when three important changes are taking place in the technologies industry that have interference in individuals' lives: one is the entrance in post-PC era, where other artifacts are used in addition to computers, such as laptops, mobile phones or tablets; the other is the cloud era, where much of the information is located in Internet-based servers; and a third, almost paradoxical to the second, is the development of services and applications based on users and content geo-referencing (locative media). Thus, activities and relationships are becoming increasingly mobile, with the internet playing a primary role in the management of these activities and relationships (Maximilien & Campos, 2012, p. 2). In this new logic, Man becomes the gatherer of information, as nomadic were gatherers of food (McLuhan, 2008 [1964], p. 288), even though in this case the man is a nomad connected to its sedentary anchors: an oscillation between local and global, between rooted and rootless (Silva, 2002, p.23). The visions of the future should therefore incorporate this new Man, with all its pendularity tendencies, experimentation and need of constant challenges, especially to what technology is concerned.

KEY TERMS AND DEFINITIONS

Information and Communication Technologies (ICT): Artefacts needed for production or exchange of information and communication to take place. Thus, it is all the hardware and software that allow individuals to acquire, store, process and distribute information by electronic means, including radio, television, telephone and computers (Collin, 2004 [1987], p. 125).

Media (Uses of): Any symbolic or technological system that enables, structures and amplifies

communication between people, but also provides access to information and content of various types.

Screen: Interface that mediates the relationship between the individual and the content he/she watches (text, image, video, sound and/or multimedia) and allows for interaction, whether by computer, mobile phone/smartphone, TV, tablet, e-book reader, clock, video and photographic camera, public placard, music player/video, among many others.

Social Relationships: Created from the moment that individuals “form families, establish friendships and fellowships, join in groups of cultural, religious, political or other affinity, create organizations and companies.” (Almeida, 2011, p. 39), having these relationships new meanings when the reference is made to online social networks.

Technology Assessment of Information and Communication Technologies

Armin Grunwald

Karlsruhe Institute of Technology, Germany

Carsten Orwat

Karlsruhe Institute of Technology, Germany

INTRODUCTION

Technology Assessment (TA) has developed over the past more than forty years against the background of challenging experiences concerning unintended and often undesirable side effects of science and technology. Development, production, social use, and disposal of technology have often resulted not only in more welfare, employment, health, and other positive achievements, but also in negative or at least ambivalent consequences, including risks to human health, society, and the natural environment. The aim of TA from the very beginning was to contribute to shaping scientific and technological progress and its transformation into innovations according to societal values and goals by investigating and assessing possible impacts and consequences *in advance*, and by transforming this knowledge into advice to decision-makers.

TA has taken up the field of Information Science and Technology (IST) as a subject of study from the 1970s on. Nowadays, this field is of central relevance to TA in a triple respect: (a) as research field *per se*, e.g. with regard to impact dimensions such as privacy, data protection, increasing use of autonomous agents, safety and security, sustainable development, intellectual property rights, regulation, societal vulnerability, *et cetera*. It is (b) also of major and even increasing importance by entering and influencing other fields of technology, e.g. energy supply, military, robotics, logistics, nanotechnology, cognitive sci-

ence, neuroscience, *et cetera*. Finally (c), several new services made available by IST developments are of high utility in TA practice of scientific projects and policy advice, e.g. in the fields of e-participation (Nentwich & König 2012). This article will provide a brief overview of TA with respect to its origin, its development, its objectives, and its current situation in general, followed by a more specific consideration of TA themes and activities in the IST field.

BACKGROUND

Technology Assessment has its roots in specific historical circumstances in the 1960s and 1970s. Activities and concerns in the U.S. political system, in particular in the U.S. Congress, led to the creation of the Office of Technology Assessment (OTA) in 1972 (Bimber, 1996). This origin of TA found a lot of successors in Europe which succeeded in establishing the European Parliamentary Technology Assessment network (EPTA, see www.eptanetwork.org).

Parallel to this development in the political system, far-ranging intellectual changes were taking place. The optimistic belief in scientific and technical progress, which had predominated in the post-Second World War period, came under pressure. Western societies were deeply unsettled by the “Limits of Growth” published by the Club of Rome in 1972, which addressed the limitedness of natural resources. In many fields, problems

with unintended side effects of technology such as pollution and severe accidents became a matter of public debate on further scientific and technological progress. In many countries, social conflicts arose on the occasion of controversial technologies such as nuclear power (from the 1970s on) and genetically modified organisms (from the 1990s on). Ethical questions led to conflicts on the development and use of new technology, in particular in the field of health and human reproduction. Issues of privacy and data protection became a field of controversy, in particular following measures of homeland protection and surveillance strategies after the 9/11 attacks. The challenges led to a complex and multi-dimensional set of objectives and rationales of TA (Grunwald, 2009).

Nowadays, the term “technology assessment” is widely used to designate a broad range of systematic approaches and methods to investigate the conditions for and the consequences of technology and to assess and evaluate them. Its task is to provide knowledge, orientation, and procedures on how to cope with challenges at the interface between technology and society *in both directions*. TA explores and assesses possible impacts and consequences of technology in a prospective manner on the one hand (technology push), and attempts to understand and take up society’s expectations and needs regarding a new technology and direct them to the relevant decision-making processes on the other hand (demand pull). The mission of TA is, thus, to contribute to “a better technology in a better society” (Rip et al., 1995), including reflecting about what the “better” could or should mean in detail and how the respective meaning of the “better” could be determined. There are three partially overlapping branches of TA addressing different targets in the overall technology governance:

1. TA has initially been conceptualized as *policy advice* (Bimber, 1996, Grunwald, 2009), which is still a strong motivation of large parts of TA. The objective is to support policy makers with advice concerning politi-

cal measures which could either influence the further development and use of technology or which themselves could be influenced by new technological developments and achievements. Frequently, policy advice in this sense is about *adequate regulation* (e.g. environmental or safety standards), changes in *research and development funding* (e.g. in the field of new and emerging sciences and technologies such as nanotechnology and synthetic biology), and *political strategies towards sustainable development* involving appropriate technologies. *Parliamentary TA* is an important sub-category of policy-advising TA, showing a high variety of institutional configurations (Cruz-Castro & Sanz-Menendez, 2006).

2. *Participatory TA* has developed approaches to involve citizens, consumers and users, actors of civil society, stakeholders, the media, and the public in different roles at different stages in technology governance (Joss & Belucci 2002, Hennen 2012). According to normative ideas of deliberative democracy, the assessment of technology should be left neither to the scientific experts (expertocracy) nor to the political deciders alone (decisionism) (Habermas 1970). Participative TA procedures are deemed to improve the practical and political legitimacy of decisions on technology. They should make it possible for decisions on technology to be accepted by a larger spectrum of society despite of remaining divergent normative convictions. Several methods have been developed and applied in recent years, such as consensus conferences, citizens’ juries, and focus groups (Joss/Belucci 2002).
3. Building on empirical research on the genesis of technology and on the theoretical framework of social constructivism (Bijker et al., 1987), the idea of *shaping technology* according to social expectations and values emerged. It motivated the development of several approaches, with Constructive TA

(CTA) being the most influential one (Rip et al., 1995). The general idea is not to address policy makers or the public, but rather to approach those groups who are directly involved in the “making of technology”, such as engineers, developers, and planners in companies and publicly-funded research and development centers. Ethical issues and social desires shall, according to this approach, be implemented in technology by enriching and orientating decision-making processes in the design and development phase of new technological systems, products, and services.

An international community evolved around the concept of TA and its various dimensions and diverse objectives, using different concepts and methodologies. Part of this community works in organizations explicitly devoted to TA (e.g., to provide advice to parliaments, cf. the EPTA network mentioned above), part of it is organized in networks (cf. www.netzwerk-ta.net), part is describing its work as systems analysis and life cycle assessment (LCA), and another part is dedicated to research in disciplinary departments of academic or research organizations, such as sociology, philosophy, political science, media studies, economics, or in the STS Community (science, technology & society studies).

TECHNOLOGY ASSESSMENT IN THE IST FIELD

Information and communication technologies (ICTs), related with advanced information science and technology (IST), are among the main driving forces for changes in all modern societies. Development and change have been associated with the penetration of ICT into almost every area of human activities. The computerization of society is characterized to date by parallel and continuing developments: firstly by building a ubiquitous and highly connected ICT infrastruc-

ture interwoven into and with other infrastructures and areas of life, secondly by the further deployment of a growing number of automated and increasingly autonomous technical systems (e.g. production systems, transportation systems, weapons systems), and thirdly by the proliferation of intelligent systems in everyday life. Such technological developments both influencing and influenced by concurrent societal changes give rise to a large manifold of initiatives and projects of technology assessment. In the following they are structured around major thematic directions of socio-technical developments. However, such developments are highly interwoven in reality and often have interrelated implications on privacy, human autonomy, replacement of humans, environmental conditions, etc.:

1. Privacy and security issues are always on the political agenda and subject of research in nearly all TA projects dealing with ICT. However, the attacks of 9/11 and the Snowden revelations have increased awareness of these issues. Technologies of governmental surveillance, biometrical identification, screening of huge data sets on indications of possible terrorist attacks benefit, on the one hand, from the rapid advance in the field of ICT. On the other hand, they provoke societal debates on securing fundamental privacy rights and limitations to or regulation of surveillance practices. Technology assessment aims at contributing to balancing security needs and societal desires to maintain the private sphere (Klüver et al., 2006). For this purpose, assessments of governmental activities of mass surveillance were conducted, from which policy recommendations were derived (Garcia et al., 2015; van den Berg et al., 2015). Related to this are TA projects (e.g., SurPRISE, Prisms, PACTS) dedicated to understanding citizens' opinions and expectations on the balancing between security and privacy and the attitudes about surveillance technologies

(e.g., Čas, 2015). In the last decades, it also became obvious that surveillance by private companies like web tracking, profiling of search engine uses, scanning the use of online services like email, etc. reached mass scale and went beyond the purpose of advertising and marketing. It raised additional privacy concerns and debates on the power of dominant global players in the field of ICT. Thus, TA studies focus on cloud computing and social network sites (Leimbach et al., 2014; Strauß & Nentwich, 2013), shedding light on their implications on privacy and security issues, especially extraterritorial issues through border-crossing data streams. Although TA has taken the role of information intermediaries (US GAO, 2013) and credit scoring (Rothmann et al., 2014) into account, the increased importance of large and combined volumes of data, technologies and practices of data mining, profiling and scoring, and other forms of analytics – often covered by the umbrella term ‘big data’ – is an area of ongoing TA research.

2. IST and the Internet have massively changed value chains and sectors in the economy with ambivalent consequences. Production, transport, logistics, division of labor across countries and continents, international trade and globalization, the workplaces of by far the most employees in industrialized countries – all these fields have been highly impacted or even enabled by the integration of IST, especially Internet-based business and organizational models. The extreme increase of economic efficiency comes at a price not only in this field. The strong increase of competition following economic globalization has, in combination with available IST services, led to adverse effects at the workplace, as a first example. Resulting requirements for permanent availability of employees, increased necessity of constant mobility, competition not only between companies but also between employees in

the same company, the enduring fear of being outranged because one’s own knowledge becomes less relevant, etc. resulted in problematic developments with a strongly increasing number of burn-outs and new debates on work-life balance. The global society’s dependence on a functioning ICT infrastructure is extremely high today and is another example of ambivalent developments. Security issues and vulnerability against hacking and cyber spying are an unwelcomed accompanying effect of the intensive use of ICT in infrastructures. In particular, the use of advanced ICT for the management of larger amounts of fluctuating energy supply from renewables and for enabling dynamic pricing models leads to investigations not only on potential enhancements with the ‘smart grid’ but also on its risks (US GAO, 2011; Ricci et al., 2012). The growing interdependencies between infrastructures, like ICT and electricity infrastructures, have been addressed, for instance, by studying the catastrophic effects of a large-scale and prolonged power outage (Petermann et al., 2011). Another example of this ambivalence can be found in the media industry, where the illegal copying of media products such as music files or videos from Internet sources had threatened the business models of that industry. The reactions were attempts to secure intellectual property rights by technical protection measures, but they got in conflict with consumer interests and rights. Meanwhile, the emergence of ‘prosumers’ actively contributing content through new Internet services has been studied as another important source of change in the media industry (Böhle et al., 2008). Technology assessment is asked in all these ambivalent developments in order to identify chances as well as risks and to provide solutions for dealing with them.

3. The integration of ICTs into society in general and the Internet in particular has also

- been related with the emergence of a “network society” (Castells, 2000). ICTs allow direct, cheap, and fast access to information resources. This aspect gave rise to hopes that citizens would be much better informed about political debates and related arguments and background knowledge, up to expectations for much more transparency in the political system, but the actual developments are ambivalent again. Social networks now have an extremely high number of members unprecedented in human history, but also gain an unparalleled position of monitoring and influencing the social behavior of a vast amount of individuals. Mobilization of pressure groups and networking possibilities supported by the Internet are ambivalent in nature as well. As exemplified during the ‘Arab spring’, this, on the one hand, allows private persons and non-governmental organizations to co-ordinate their activities against powerful institutions. On the other hand, these new opportunities can also be used by terrorist and other radical movements. Technology assessment is therefore not only faced here with a lot of tasks of monitoring and assessing changes in social life, but also with making use of ICT to realize own objectives in political process.
4. More and more visions of ‘ubiquitous computing’, ‘pervasive computing’, and ‘ambient intelligence’ are being realized today, mainly by related concepts and developments that are named with other keywords. The further miniaturization and reduced costs for tags, sensors and connected devices, advancements of ‘intelligent’ systems and components, and the connectivity via diverse forms of Internet communication enable business and organization models called ‘smart home’, ‘smart car’, ‘smart traffic’, ‘smart cities’, etc. as well as ‘Internet of things’ or ‘Internet of everything’. They are realized in almost every area of life including those with great intimacy. Issues of TA research on ubiquitous computing (Bizer et al., 2006; Friedewald & Raabe, 2010) are not getting obsolete but more and more relevant, necessitating focused assessments of the changes in these areas of life. Other issues for TA are emerging, such as the dependence on platforms, issues of accountability, transparency, and trust, or the (ongoing) need for reflecting on privacy conceptions. Also the continuing miniaturization makes elements of ICTs more and more invisible to the human eye. Nanotechnology will certainly support and accelerate these developments (Grunwald, 2012). Such miniaturization, in connection with the limited human eyesight, and the networking of surveillance equipment could substantially obstruct the present control options and regulations for protecting personal data or even make them completely obsolete. The passive surveillance of humans might be supplemented in the more distant future by active surveillance (that the targets themselves might not notice), such as if it proved possible to construct direct technical access to the nervous system or the brain.
 5. Miniaturized technologies including IST and based on nanotechnology offer, according to Roco and Bainbridge (2002), far-reaching perspectives for perceiving even the human body and mind to be formable and for improving them through precisely targeted technical measures. In the idea of “NBIC convergence”, nanotechnology, biotechnology and genetic engineering, information and communication technology, and cognitive science and brain research are assumed to converge and, as a consequence of this convergence, to create radically new opportunities. An example is “neuro-enhancement,” which refers to an enhancement resulting from an implant or medication connected either to the nervous system or directly to the brain. First steps are the technical replacements of natural organs. Examples are cochlear or retinal

- implants to first technically compensate for a *loss* of sensory function (in these cases, of an eye or an ear). As a result of advances in nano-informatics, such as miniaturization or the increased capacity of implants to take up and process data, the spatial dimensions, and performance of the neuro-implants will approach those of natural systems. New IST developments are keys to possibly realize those visions. Technology assessment in this field is more or less to be conceived as a “vision assessment” accompanying the scientific development in its very early stage and helping to better understand chances as well as risks (Grunwald, 2012).
6. Health services are particularly sensitive with regard to the private sphere. The development of small units for preparing diagnoses – “lab on a chip” – can make it possible for comprehensive personalized diagnoses and prognoses to be prepared on the basis of a person’s health data (van Merkerk, 2007). The demands placed on data privacy and thus on the protection of one’s privacy must therefore be high. In particular the strongly increasing fields of tele-medicine and ubiquitous computing in healthcare lead to growing challenges to ensure privacy and to avoid possibilities of misuse (Orwat et al., 2008).
 7. Progress in IST can lead to the loss of human autonomy because it provides technological systems with more and more autonomy for decision-making as is the case in the fields of autonomous robots and autonomous software agents. Self-determination regarding information, a part of an individual’s autonomy, can be limited by technology, just as technological means can be used to gain external control over humans. In particular, the word “technicalization” is frequently associated with a subordination of man to technology, a loss of control, a discontent caused by man’s dependence on technology, and a loss of individuality, emotionality, and spontaneity. Current and future IST developments require thinking anew about the relations between humans and technology with respect to the distribution of autonomy (Decker & Gutmann, 2012; Wiegerling, 2011), which is part of the business of technology assessment involving the ethics of technology (Grunwald, 2012).
 8. IST-enabled innovations have an important place in the debate on e-participation and e-parliament. Petitioning, for example, cannot be simply written off as a relic of a bygone age. Precisely because society is becoming increasingly complex, petitions can provide citizens with an additional – and sometimes also “ultimate” – possibility of drawing attention to grievances and injustices and also submitting suggestions for solving a specific problem. The occasion that prompted the Office of Technology Assessment at the German Bundestag (TAB) to conduct intensive research into the subject of electronic petitioning was the introduction of “public petitions” by the German Bundestag in 2005. These petitions are submitted electronically, published on the Internet, and can be signed and debated on the e-petition platform of the German Bundestag (see www.tab-beim-bundestag.de). Technology assessment was intensively involved in accompanying the process and development of e-petitioning at the German Bundestag by evaluating case studies from other parliaments, by empirical studies on electronic participation and, as is the main task of parliamentary technology assessment, by developing options for parliamentary action (Lindner & Riehm, 2011; Beckert et al., 2011; Riehm et al., 2014).
 9. The huge amount of new technical artifacts related with ICTs such as computers, mobile phones, and servers, which were quickly integrated into added value chains, into the workplace, into education, and into households, influences material flows at the global level as well as the need for energy supply

and thus touches upon ecological concerns. The short life-time of many of these artifacts increases related problems of waste disposal and recycling. While the *Leitbild* of sustainable development calls for more environmentally compatible production and consumption patterns, developments in real society related with ICT seem to go into the opposite direction. Initial hopes on a “de-materialisation” (Berkhout & Hertin 2004) of the economy accompanied by reduced mass flows and energy demand did realize only to a limited extent up to now. An important objective of TA in the field of ICT is, therefore, to help shaping new ICTs to better fit the requirements of sustainable development (Hilty & Ruddy 2002). The method of Life Cycle Assessment and related approaches are of high importance in this respect. Recent research and development efforts are targeting a “Green Information Technology,” in particular aiming at much higher energy efficiency. Beyond regarding individual technologies, there are attempts to better reconcile the development of IST and ICT in the overarching framework of a sustainable information society (Fuchs, 2006). Smart solutions combining technologies, services, and assumed user behavior are developed with the intention, for instance, to reduce greenhouse gas emissions, save energy, enable participation, and reduce poverty. In particular in the context of the transition of energy systems, there are high hopes that ICT solutions contribute to enhancements of energy efficiency (Schippl & Weinberger, 2009).

FUTURE RESEARCH DIRECTIONS

A major development of recent years has been the growing importance of the ideas of “Responsible Development” in scientific and technological

advance and of “Responsible Innovation” in the field of new products, services, and systems (von Schomberg, 2012). They take over the perspective of “shaping technology” mentioned above, extending it to early stages of research and development and bringing together TA, ethics, and STS research.

The notion of Responsible Innovation and related terms will receive increased attention over the next years. In particular, it will be applied to new and emerging sciences and technologies. Because the field of IST again and again creates new and ambitious visions and developments, there will be a strong focus on this field. Some illustrative examples of technological fields with strong IST involvement which need further accompanying reflective analysis are all ‘smart’ developments, the ‘Internet of everything’, the burgeoning importance ascribed to data, increasingly autonomous agents, interdependencies between ICT and other critical infrastructures, or bridging the gap between IST and the human brain, to name but a few.

CONCLUSION

From its very beginning, TA has been confronted with expectations of contributing to research, development, and innovation by adding reflexivity, by including perspectives different from those of scientists, engineers, and managers, by taking into account (even uncertain) knowledge about consequences and impacts of new science and technologies, and by transforming all these elements into advice to policy makers and society. TA has successfully developed several conceptual approaches, methods, and institutional settings to cope with those expectations. Regarding ongoing developments such as

- The further acceleration of scientific and technological advance, in particular in the field of IST,
- The rapidly growing and complexity-increasing penetration of nearly all fields

of technology and areas of life with IST (energy, health, mobility, logistics, homes, bodies, etc.),

- The increasing need for early reflection on economic and social, but also on cultural and ethical impacts of new technologies in industrialized countries,
- The also increasing claim of many citizens and organized groups in modern societies to be involved in decision-making processes on new technologies,
- The worldwide request for a more sustainable development, and
- The new roles of countries such as China, India, Brazil, and South Africa and their research and innovation systems,

it seems obvious that (1) technology assessment will have to further develop in order to be able to meet these challenges, and that (2) IST will play an even more important role in future TA compared to the past because of their cross-cutting, pervasive, and enabling character.

KEY TERMS AND DEFINITIONS

E-Participation: Using ICTs for supporting participation processes in government and governance. The need for broader participation has emerged over the past decades predominantly in Western societies. ICTs provide means to allow a much larger number of people to participate.

Governance: The process of opinion-forming and decision-making. In nation-states, these processes and systems are traditionally administered by the government. Currently we witness a strong movement to better involvement of citizens, stakeholders, and civic society in those processes.

Information Society: The creation, distribution, use, integration, and manipulation of information is of major economic, political, and cultural importance. Its main medium is the widespread use of information technology.

Privacy: The ability of individuals or groups to control the use of personal information about themselves or to keep such information in a defined space.

Responsible Innovation: A term pointing to the need for shaping technology and innovation with respect to criteria of responsibility and human values.

Sustainable Development: The kind of development that meets the needs of the present without compromising the ability of future generations to meet their own needs (WCED, 1987).

Technology Assessment (TA): A scientific, interactive, and communicative process which aims to contribute to the formation of public and political opinion on societal aspects of science and technology (Decker & Ladikas, 2004).

H

Towards an Interdisciplinary Socio-Technical Definition of Virtual Communities

Umar Ruhi

University of Ottawa, Canada

INTRODUCTION

Originally defined as “*social aggregations on the Internet*” (Rheingold, 1993), virtual communities (VCs) refer to interactive online spaces that can potentially enable high levels of information sharing, communication, and social interactions among their members. VCs can also be described as computer supported social networks (Garton, Haythornthwaite, & Wellman, 1997) or “*gathering spots*” on the Internet where individuals and organizations can share common interests and meet differentiated user needs and wants (Baim, 2006).

Since their earliest inception, VCs have been recognized as an important facet of the digital economy, and as a critical success factor for e-Commerce (Figallo, 1998; Hagel & Armstrong, 1997; Preece, Abras, & Maloney-Krichmar, 2004; Ridings & Gefen, 2004). VCs can potentially provide value to their individual members and sponsoring organizations through a variety of internal-facing business applications, such as knowledge sharing and organizational learning, as well as external-facing online activities, such as the provision of commercial and government services (Bughin, 2007; Lee & Suh, 2015; Mačiulienė & Skaržauskienė, 2016; Petouhoff, 2009).

Due to the wide-ranging use-cases and potential benefits of VCs, they have been a subject of study in many academic disciplines, including sociology, psychology, management, communication, computer science, and information systems. The objective of this chapter is to examine various streams of research that have studied VCs, and to facilitate the reader’s understanding of

VCs through an explanation of their underlying concepts and their fundamental properties. Toward this, the chapter specifically reviews the discourse on VCs in research fields adopting a socio-technical lens of analysis, and proposes a socio-technical definition of VCs.

The discussion in this chapter starts with a characterization of VCs from an information systems perspective. This is followed by a brief synopsis of research fields that have form the basis of socio-technical investigations of VCs. Finally, the chapter reviews literature domains that draw upon these research fields and cites seminal definitions from these domains to deliberate and propose an interdisciplinary socio-technical definition of VCs.

Within the various disciplines that study VCs, many researchers often use the terms virtual communities, online communities, web communities, cyber communities, electronic communities and e-communities interchangeably to refer to the same phenomenon (Jones & Rafaeli, 2000; Schoberth, Preece, & Heinzl, 2003). For purposes of this review, our survey of literature includes research that has been conducted surrounding these various notions of VCs. Furthermore, this chapter uses the terms virtual communities and online communities interchangeably.

BACKGROUND

Despite the absence of an agreed upon definition of VCs across research studies, the presence of a technology platform that facilitates interactions

DOI: 10.4018/978-1-5225-2255-3.ch371

Table 1. Virtual community attributes as elements of an IT artifact

Defining Elements of an IT Artifact	Examples of Attributes of Virtual Communities
Information & Communication Technologies	■ Websites and portals hosting the virtual community ■ Groupspace platforms such as social networks, discussion forums, blogs, wikis, mailing lists, newsgroups. ■ Communication tools such as instant messaging and interactive chat applications
Tasks	■ Information exchange in the form of sharing knowledge, asking and answering questions, providing commentary, and collaborating on new content ■ Social interactions in the form of networking with other members, forming relationships, and seeking and providing emotional support
Task Structures	■ Administrative policies and controls ■ Interaction norms and etiquette ■ Technology usability and accessibility ■ Scope of information exchange and social interaction (diverse/narrow) ■ Extent of participation (active/passive)
Task Context	■ Member motivations and interests ■ Membership duration ■ Self-efficacy in technology use and personal knowledge and expertise ■ Member trust levels and sense of community

among members is considered to be a main characteristic of online communities (Donath, 2005; Preece, 2001a; Preece, 2001b). Various information and communication technologies (ICTs) can be used in VCs – including, websites, computer networks, email lists, Usenet newsgroups, discussion forums, Internet chat applications, and networked databases (Coon, 1998; Lapachet, 2001). Additionally, modern technology platforms such as social networking sites, weblogs (popularly known as blogs) for user generated content, and wikis for online collaboration have also been considered in the list of potential technologies that can spawn a VC (Blanchard, 2003; Brailas, Koskinas, Dafermos, & Alexias, 2015; Buss & Strauss, 2009 ; Mačiulienė & Skaržauskienė, 2016). These various technology platforms and their underlying features and functions that enable VCs have been studied by information systems (IS) researchers over a long time. In this section, we offer a characterization of VCs from an IS perspective.

IS research can be considered as the study of the effective use of ICTs and their potential impact on human, organizational, and social world (Gregor, 2006; Hirschheim & Klein, 2003; Khazanchi & Munkvold, 2000). At the theoretical core of IS research is the concept of an *IT artifact*, which

refers to ICTs that act as enabling infrastructure for people and organizations in driving their individual activities and business processes, and ultimately affecting their overall performance and satisfaction levels (Bacon & Fitzgerald, 2001). In viewing VCs as IT artifacts, we adopt Benbasat & Zmud's (2003) normative perspective of the field of IS, and their delineation of the scope of IS research as relating to the IT artifact's immediate nomological network (capabilities, perceptions, uses, practices, behaviour, and impacts linked to the IT artifact). Using this orientation, VCs can be examined in terms of their underlying ICTs and their use by members, while also considering the context and structure of tasks embedded within the VCs and performed by their members. To illustrate the conceptualization of VCs as IT artifacts, Table 1 provides examples of attributes of VCs that align with the defining elements of IT artifacts.

Based on the conceptualization of VCs as IT artifacts, it can be seen that the task structure and task context elements of the IT artifact have a strong sociological basis. To effectively address this dual sociological and technological nature of the IT artifact pertaining to VCs, a socio-technical perspective has been strongly recommended in academic research (Dannecker,

Leimeister, Konana, & Rajagopalan, 2007; Koh, Kim, Butler, & Bock, 2007) and industry practice (Gossieaux & Moran, 2008; Petouhoff, 2009). The socio-technical perspective in IS research is based on the premise that information systems comprise behavioural as well as technological sub-systems that need to be addressed in unison while investigating pertinent IS related phenomena (Becker, Niehaves, & Janiesch, 2007; Lee, 2000). Our ultimate aim in this chapter is to propose a socio-technical definition of VCs that draws upon various streams of research literature.

THEORETICAL UNDERPINNINGS IN SOCIO-TECHNICAL RESEARCH ON VIRTUAL COMMUNITIES

VCS and their underlying facets have been investigated in various research fields, including, sociology, psychology, computer science, information systems, information science, communication studies, economics, management science, and marketing management. In a bibliometric study, Laine (2009) found that the greatest number of publications related to VCs were in the technology related research fields of information science, information systems, and computer science, followed by publications in business and management. Similarly, in a more extensive search across multiple electronic databases, Iriberry and Leroy (2009) found that studies of VCs were more common in information systems and business research areas, but that a strong grounding in the psychology and sociology extant literature also existed.

While a comprehensive coverage of VC research in all these fields is beyond the scope of this chapter, we specifically focus on fields that form the basis of socio-technical research in the extant VC literature. Toward this, based on the commonalities in themes and focus of different VC studies, we classify the extant research on VCs into four categories, namely, i) sociological/psychological; ii) technological; iii) business/management; and iv) economic perspectives.

Table 2 below presents a summary of a sample of studies from these four perspectives by outlining the core issues and common theoretical constructs addressed by each, as well as sample references and top cited publications¹. A brief synopsis of each of the four perspectives follows.

The *sociological/psychological* research perspective of VCs is primarily concerned with the social structure of collectives and the nature of relationships within those collectives. In deliberating social practices and outcomes of participation in VCs, this perspective makes use of concepts from human cognitive and affective processes that lead to the development of psychological trust and sense of community among members. For instance, Etzioni & Etzioni (1999) examine aspects of bonding and culture in a VC and define it through two attributes, namely, a web of affect-laden relationships encompassing group of individuals (bonding), and commitment to a set of shared values, norms, meanings and a shared historical identity (culture). Frameworks based on social capital theory (Coleman, 1988; Jacobs, 1965; Putnam, 1995) and social cognitive theory (Bandura, 1986; Compeau & Higgins, 1995) are frequently used to discuss the development of ties through relational capital including trust, as well as cognitive capital through increased self-efficacy over the course of participation in a virtual community. From a social psychology viewpoint, researchers have also used the concept of psychological sense of community (McMillian & Chavis, 1986) to deliberate the presence of a similar affective and attitudinal construct in the context of VCs (Blanchard, 2007; Blanchard & Markus, 2002; Obst & White, 2004). VC research shows sense of community to be an essential factor in the success and sustainability of VCs (Bagozzi & Dholakia, 2002; Blanchard, 2007; Preece et al., 2004).

Researchers investigating VCs from a *technological* research perspective refer to them in terms of the functionality of the software supporting the interactions in the community (Flake, Lawrence, Giles, & Coetzee, 2002; Lazar, Tsao, & Preece,

Table 2. Research perspectives and principal topics in virtual community studies

Research Perspective	Core Issues	Common Theoretical Constructs	Sample References
Sociological / Psychological	■ Social structure of virtual community environment ■ Factors affecting online social processes and relationships ■ Comparisons with face-to-face communities ■ Cognitive and affective processes of trust building and psychological bonding among community members	■ Social Capital (Structural, Relational, Cognitive) ■ Social Ties (Centrality, Degree, Density etc.) ■ Member Motivations and Social Behaviour ■ Sense of Community	■ Rheingold (1993) ■ Wellman et al. (1996) ■ Romm et al. (1997) ■ Etzioni & Etzioni (1999) ■ Kollock (1999) ■ Wellman & Gulia (1999) ■ Turner et al. (2001) ■ Blanchard & Markus (2003) ■ Eysenbach et al. (2004) ■ Obst (2004) ■ Ling et al. (2005)
Technological	■ Use of appropriate technology platforms for online interactions ■ Interactivity and usability of virtual community interface ■ Supporting sociability through technology tools and features	■ Usability and Sociability ■ Technology Acceptance Factors (Ease of Use, Usefulness, Intention to Use) ■ IS Success Factors (System Quality, Information Quality, System Use, User Satisfaction)	■ Erickson & Kellogg (2000) ■ Ridings et al. (2002) ■ Preece (2001b) ■ Flake et al. (2002) ■ Yoo et al. (2002) ■ Ridings & Gefen (2004) ■ Moore & Serva (2007) ■ Lin & Lee (2006) ■ Wise et al. (2006) ■ Jin et al. (2007) ■ Chen (2007)
Business / Management	■ Fostering relationships with consumers through online communities ■ Leveraging positive consumer behaviour in online customer reference groups ■ Engaging customers and employees to contribute in business functions such as R&D and Sales	■ Consumer Behaviour ■ Loyalty and Commitment ■ Purchase Decisions ■ Knowledge Contribution ■ Co-creation of products and services ■ Competitive Advantage	■ Armstrong & Hagel (1996) ■ Kozinets (1999) ■ McWilliam (2000) ■ Kozinets (2002) ■ Bauer & Grether (2005) ■ Wasko & Faraj (2005; 2000) ■ Lu et al. (2008) ■ Porter & Donthu (2008) ■ Petina et al. (2008)
Economic	■ Sustainability of virtual communities as economic entities within a social context ■ Study of virtual community members as rational utility-maximizers ■ Mechanisms for value creation and resource conversion into benefits for collectives	■ Return on Investment ■ Membership Size ■ Communication Activity Levels ■ Community Growth	■ Hagel & Armstrong (1997) ■ Kollock (1999) ■ Balasubramanian and Mahajan (2001) ■ Butler (2001) ■ Cothrel (2000b) ■ Gu & Jarvenpaa (2003)

1999), as well as issues of usability of the application interface (Chen, 2007; Wise et al., 2006). To bring balance to this approach, through her seminal research work on VCs, Preece (2001c; 2004; 2003) urges system designers to concentrate on sociability aspects of VCs to help understand the social interaction requirements and preferences of community members. Parallel streams of research adopting the technological research perspective exploit the application of more well-established IS models to investigate member participation.

Theoretical constructs from the technology acceptance model (TAM) (Davis, 1989) have been used repeatedly in various contexts to link the constructs of perceived usefulness and perceived ease of use of VC technologies to a member's behavioural intention to continue participation in the VC (Hsu & Lu, 2007; Huang, Hsu, & Yen, 2008; Lin, 2006; Lin, Chiu, & Tsai, 2008). Similarly, constructs of information quality and system quality from the information systems success model (DeLone & McLean, 1992, 2003; Petter, DeLone, & McLean,

2008) have been conceptualized and corroborated to affect the overall satisfaction with and use of the VC (Lin, 2008; Yoo et al., 2002).

Through the *business/management* research perspective of VCs, studies explore applications of online communities in a multitude of business functions including marketing, sales, research and development (R&D), and human resources (Armstrong & Hagel, 1996; McWilliam, 2000; Spaulding, 2009). In an integrated framework to highlight the benefits of VCs in a business context, Spaulding (2009) used the theory of social contract to explain the applications of VCs in each activity across a firm's value chain (Porter, 1980). More specifically, marketing related studies on VCs focus on brand communities and online consumer reference groups. The development of communal bonds among members of a VC to help promote a firm's products and services are a common area of discourse in the extant research literature (Dholakia, Bagozzi, & Pearo, 2004; Kozinets, 1999). In terms of applications for R&D, the value of open innovation communities in improving and advancing products and service offerings has also been discussed (Fuller, Bartl, Ernst, & Muhlbacher, 2004; Ramaswamy, 2009). Finally, a major area of research in the business/management perspective relates to knowledge sharing and contributions in online communities of interest and electronic networks of practice (Wasko & Faraj, 2005; Wasko & Faraj, 2000). More recently, researchers are starting to explore the paradigm of collaborative intelligence in VCs through studies of new technology platforms such as wikis and other social media applications (Brailas et al., 2015; Hoegg, Meckel, Stanoevska-Slabeva, & Martignoni, 2006; Lee & Lan, 2007).

Lastly, under the *economic* research perspective, VCs are viewed as economic entities embedded in a social environment in which value creation and resource utilization aspects can be improved through greater member contributions of informational content (Balasubramanian & Mahajan, 2001). This perspective assumes the actions of VC constituents conform to neoclassi-

cal principles that view society as a collective of egoist entrepreneurs with individual rationality and incentive compatibility (Gu & Jarvenpaa, 2003). As an example of the treatise of VCs from an economic research perspective, consider the research exposition by Balasubramanian and Mahajan (2001) where the authors argue that it is the strength of social interactions and focus on specific market activities in VCs that can help develop economies of scale and lead to a competitive advantage for the sponsoring firm. Another theoretical construct frequently seen in studies pertaining to the economic research perspective is membership size, where resource availability is regarded as directly proportional to membership size and a critical mass of members is required to sustain the interactions in a VC over the long term (Butler, 2001). The concept of return on investment (ROI) has also been discussed using the economic research perspective. Here, the ROI of a VC is viewed as a combination of factors, including: the incremental value of a business (with and without the VC), the size of the community membership, the magnitude of active regular interactions, and the rate of conversion of site visitors to members who engage in commercial transactions (Cothrel, 2000b).

SOCIO-TECHNICAL LITERATURE DOMAINS DISCUSSING VIRTUAL COMMUNITIES

Towards helping us put forward a holistic socio-technical definition of VCs, this section presents a summary of four interdisciplinary literature domains that draw upon some of the theoretical concepts from research disciplines identified in the previous section. These include: i) Computer Mediated Communication (CMC), ii) Community Informatics (CI), iii) Knowledge Management (KM), and iv) Internet Marketing (IM)². An overview of the scope and exposition of research in these four domains is provided below.

Researchers who approach VCs from a *computer-mediated communication (CMC)* standpoint typically conceptualize them as technology tools that facilitate human communication via computers. Primarily based on a technological research perspective, they concentrate their efforts in describing different forms of synchronous, asynchronous or real-time interaction tools used in online communities to exchange text, images, audio and video (Hiltz, 1998; Morris & Ogan, 1996; Olson & Olson, 1998; Sproull & Kiesler, 1991). Additionally, CMC research has also answered the call for the inclusion of sociability (Preece, 2001a) in the overall treatise of virtual community specifications, and there is a trend towards recommending solutions that incorporate sociability as well as usability in the design of VCs (Donath, 2005; Preece, 2001a; Preece, 2001b). Overall, the viewpoints adopted in CMC research can be seen as being geared towards the development of VCs from a human computer interaction (HCI) perspective, as they emphasize the functionality and usability aspects of the interaction media in VCs while taking into account the alignment of these technologies with the sociability objectives of the VC constituents.

The fast emerging interdisciplinary field of *community informatics (CI)* pertains to the design and application of ICTs that can be utilized to enable community processes and achieve community objectives, including a community's social, economic, cultural, or political goals (Gurstein, 2000, 2004). By that token, VCs are often regarded as specific applications in community informatics (Marshall, Taylor, & Yu, 2004; Pitkin, 2001). On a macro level, CI researchers have studied the applicability of VCs and related technologies to facilitate the progress of local, regional and national communities, with frequent discussions of ideas of civic participation, economic development, education and learning, and community service delivery (Gurstein, 2000; Keeble & Loader, 2001; McIver, 2003; Taylor, 2004). Additionally, recent literature in CI has significantly contributed to the body of knowledge outlining success factors

and best practice models for the administration of VC projects (Carroll & Rosson, 2007; Romm & Taylor, 2001). As such, researchers in the field of CI stress the importance of sociological as well as technological ingredients in the overall success of VCs which makes this literature area a worthwhile source of information on socio-technical perspectives of VCs.

Knowledge Management (KM) related research on VCs has primarily explored the effectiveness of different knowledge sharing processes in various online community settings, including virtual communities of practice (Davies, Duke, & Sure, 2004; Droschl, 2004; Ruhi, 2008; Wasko & Faraj, 2005; Wasko & Faraj, 2000), online learning communities (OLCs) (Cothrel, 2000a; Palloff & Pratt, 1999), and online knowledge communities (OKCs) (Bieber et al., 2002; de Vries & Kommers, 2004). Common to the research discourse for these different types of VCs is the discussion on processes and technologies that facilitate information and knowledge sharing. The sharing of tacit knowledge in such communities is often considered to be a socio-psychological process for which effective social activities need to be instigated and sustained as an integral part of the community's institutionalization. For instance, success of knowledge contributions is often framed within the context of social capital constructs such as structural, relational and cognitive capital, and studies discuss how different technology and management interventions can be adopted to improve these social capital dimensions to enable higher level and better quality knowledge contributions (Wasko & Faraj, 2005; Wasko & Faraj, 2000). Hence, a great number of research expositions found in the extant KM literature on VCs also adopt a socio-technical viewpoint of interactions and activities in online communities, and this literature domain constitutes an effective basis for a definition of VCs germane to a socio-technical lens of analysis.

Finally, as an applied field of research, *Internet Marketing (IM)* has been at the forefront of VC research since the earliest conception of

online communities in the commercial realm. Content, Community, Commerce – the 3 Cs of electronic commerce as they are widely known in the internet marketing literature, have together been regarded as the critical success factors that businesses need to manage in order to prosper in online marketing and sales (Chaffey, Mayer, Johnston, & Ellis-Chadwick, 2002). Jagannathan et al. (2002) refer to community as an *“important driver leading to a condition where e-Commerce can occur”*. The focus of discussions in the IM literature is primarily concerned with the generation and maintenance of customer traffic while finding new ways to penetrate current market segments and discover new ones. Recent explorations of consumer reference groups and online customer service communities have focused on motivational factors that facilitate the involvement of customers in various business processes across the sponsoring firm’s value chain (Goel & Mousavudin, 2007; Petouhoff, 2009). Practices related to improving user loyalty, enabling better feedback on products and services, accessing beta testers and early adopters, and promoting word-of-mouth have produced valuable guidelines and principles that relate the role of technology to sociological and psychological consumer behaviour processes (Araujo, 1999). Therefore, these studies from the internet marketing literature domain can also prove useful in proposing a socio-technical characterization of VCs.

AN INTERDISCIPLINARY SOCIO-TECHNICAL DEFINITION OF VIRTUAL COMMUNITIES

From the review of the selected research perspectives and literature domains in the previous sections, it is apparent that although researchers from these subject areas offer discourse-specific descriptions of VCs and their applications, there is a distinct socio-technical undertone to their treatise of VCs. As such, these streams of research offer an adequate basis from which to devise an

interdisciplinary socio-technical definition of VCs. In deliberating such a definition, a review of some of the definitions of VCs from the extant literature in the four areas above was conducted to reconcile and elaborate the primary notions of VCs. As a summary, various definitions proposed by researchers in the four literature domains are contrasted in Table 3.

Among the plethora of definitions that were found, those presented in Table 3 were carefully selected to reflect the viewpoints across the four literature domains. These definitions also vary in the style of their attribution – while some provide ascriptive characterizations of VCs, others are based on their descriptive representations. Researchers employing ascriptive portrayals of VCs focus on their underlying social constructions including the motivations of the members, and the interactions and exchanges among them. This is in contrast to the descriptive accounts of VCs which primarily emphasize their functional goals, often in a technophilic context, highlighting technology features of VCs over their social interaction aspects.

Despite the miscellany of depictions of virtual communities seen in the definitions above, several similarities can be highlighted. These similarities are briefly noted below to conceptualize our proposed definition of VCs.

The first similarity is the aggregation of *“participants”* (the first component of the proposed definition) who share a common *“purpose”* (the second component of the proposed definition). The term participants is used to incarnate both individuals as well as organizations who may partake different roles in a VC. Further, the concept of interaction is logically embedded in the term participation as well. The interactions in a VC revolve around a common purpose in VCs. This common purpose can subsist in a VC in the form of *“shared interests, expertise, problems, ideas, or passions”* (Nilan, Zakari, Guzman, & Zakaria, 2004).

A second similarity is that interactions between members of a virtual community are me-

diated through various technologies. Hence, the presence of a mediating technology “*platform*” constitutes the third component of the proposed definition. Note that most researchers realize the importance of non-computer based technologies in mediating interactions among community members (De Souza & Preece, 2004; Kollock, 1998; Rheingold, 2000). These technologies can include various audio/video conferencing tools, as well as advanced mobile technologies. Hence, the proposed definition of a technology platform is not restricted solely to computer based technologies.

Thirdly, a salient feature that can be noted from Preece’s original (2001a) and subsequent (2001b; Preece et al., 2004) definitions, is the notion of norms and policies. Sociologists assert that the policies and norms in a VC are in fact an ecological extension from traditional real-life communities (Brint, 2001; Valtersson, 1996). Hence, the idea of “*protocols*” constitutes the next essential component of the proposed definition.

Last, an important characteristic of VCs that has recently come under intense discussion is the notion of a sense of belonging or a sense of com-

Table 3. Ten Seminal definitions of virtual communities from various literature domains

Source	Definition	Related Literature Streams			
		CMC	CI	KM	IM
Bagozzi & Dholakia (2002)	Virtual communities [are] mediated social spaces in the digital environment that allow groups to form and be sustained through ongoing communication processes.				●
Bieber et al. (2002)	[A] virtual community include[s] anyone actively interested in, or associated with, a group formed around a particular domain of interest. Dispersed or local, the community requires electronic support to implement a continuous meta improvement strategy in its services.			●	
Cothrel & Williams (1999)	An online community is a group of people who use computer networks as their primary mode of interaction.			●	
Gurstein et al. (2002)	Virtual communities serve a diversity of groups, including people with common interests; groups fostered by particular organizations, industries or marketplaces; those who face similar life circumstances; as well as those who simply wish to socialize, play games or participate in fantasy experiences together on-line.		●		
Hagel & Armstrong (1997)	Virtual communities are computer-mediated spaces where there is a potential for an integration of content and communication with an emphasis on member-generated content.	●			●
Jones & Rafaeli (2000)	Virtual Publics are symbolically delineated computer-mediated spaces, whose existence is relatively transparent and open, that allow groups of individuals to attend and contribute to a similar set of computer-mediated interpersonal interactions.		●		
Lee et al. (2003)	[A virtual community] is a cyberspace supported by computer-based information technology, centered upon communication and interaction of participants to generate member-driven contents, resulting in a relationship being built up.		●		
Plant (2003)	A collective group of entities, individuals or organizations that come together either temporarily or permanently through an electronic medium to interact in a common problem or interest space	●			
Preece (2001a)	An online community consists of people, who interact socially; a shared purpose; policies; and computer systems, to mediate social interaction.	●			
Rheingold (1993, 2000)	[Virtual communities are] social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace.	●			

munity among VC members (Bagozzi & Dholakia, 2002; Blanchard & Markus, 2003; Koh & Kim, 2003). Also described as a consciousness of kin that acts as an intrinsic connection to other members, researchers attribute this sense of affiliation with the shaping of a member's behaviours in the online community (Kleinman, 2000; Wellman & Gulia, 1999). Feelings of belongingness and self-identity have been regarded as important elements in instilling a psychological ownership among VC members, subsequently leading to improved member outcomes in VCs (Lee & Suh, 2015). Therefore, the "*persona*" that a VC instils among its members to make them feel part of the community and help them express their self-identity constitutes the final component in the proposed definition. Therefore, the "*persona*" that a VC instils among its members to make them feel part of the community constitutes the final component in the proposed definition.

Together, these salient attributes of a virtual community (the 5 Ps discussed above)³ are assembled into components of a nascent definition along the lines of an ascriptive socio-technical

characterization of VCs: *A virtual community is an aggregation of "participants" (individuals or organizations) with a shared "purpose", who have their interactions mediated through a technology "platform" and guided by collective "protocols", and who embrace a cooperative membership "persona" in their online interactions.*

Figure 1 depicts the components of the proposed definition as interlocking gears driving one another, and the interactions constituting member participation in the VC. It is hoped that the proposed definition and its various underlying components can act as a touchstone to guide future research expositions on VC. Some suggestions for the use of this definition are provided in the next section.

FUTURE RESEARCH DIRECTIONS

The definition of VCs proposed in this chapter recognizes that social and technical interaction features in online communities are largely interwoven, and together, these factors play an important role in determining the uses and outcomes of VC initiatives. By drawing attention to various socio-technical facets of VCs, it is hoped that the components in the proposed definition can help VC researchers adopt amongst a multitude of outlooks while investigating VCs.

For IS research in particular, our definition espouses an IT artifact viewpoint of VCs, and it includes various aspects linked to the IT artifact's immediate nomological network. The platform component links to the capabilities of the artifact, while the participants and purpose component characterizes various uses, practices, and behaviour linked to VCs. Similarly, the persona and protocols components of the definition symbolize the perceptions and impacts aspects linked to the use of the IT artifact. Overall, the proposed definition can potentially allow an investigation of VCs in terms of their underlying ICTs and their use by members, while also considering the context and structure of tasks embedded within the VCs and performed by their members.

Figure 1. Components of a socio-technical definition of virtual communities

Our proposed definition can also be utilized as a conceptual framework to provide an analytical foundation for studying member participation in VCs. By combining aspects of social processes as well as attributes of technology artifacts, our definition can complement other analytical frameworks for VCs such as the *online community framework (OCF)* by De Souza & Preece (2004) (also see Akoumianakis, 2008), and the *evidential conceptual model of online community* by McArthur & Bruza (2001). Both these frameworks include broad-based thematic concepts related to the goals and needs of VC members, technology infrastructure requirements for VCs, and human interaction processes in VCs. Our proposed definition also incorporates all of these elements. Therefore, through this definition, we hope to provide an alternative or complementary abstraction of a VC in terms of its basic building blocks.

On the whole, the proposed definition offers a structured and holistic socio-technical lens of analysis for future research pertaining to VCs. Subject areas related to technology development, functionality adoption, implementation and outcome assessment, or practice institutionalization can be facilitated through a framework based on this definition.

CONCLUSION

This chapter offers a summary of various research disciplines and literature domains that investigate VCs from a socio-technical perspective. Subsequently, definitions from seminal research studies are synthesized to propose an interdisciplinary socio-technical definition of VCs.

The proposed definition of VCs can potentially act as a high-level abstraction of online communities – highlighting their five core facets, namely, participants, purpose, platform, protocols, and persona. Together, these facets constitute a structured and holistic socio-technical lens of analysis

that can be used in future research pertaining to VCs. Furthermore, through a focus on one of more underlying elements, the proposed definition can serve as a useful conceptual aid for: i) analyzing the enabling and inhibiting factors in the evolution of VCs; ii) examining different types of member and technology interactions that develop in VCs over time; iii) investigating factors that affect the uptake and outcomes of VC initiatives; and iv) exploring key success factors for effective governance and operation of VCs.

KEY TERMS AND DEFINITIONS

Computer-Mediated Communication: Any form of data exchange (text, images, audio, or video) among two or more end-users utilizing different ICTs for synchronous, asynchronous or real time communication with one another.

HCI (Human-Computer Interaction): An interdisciplinary field of research and practice

concerned with the design, implementation, use, and evaluation of interactive ICTs.

ICTs (Information and Communication Technologies): An umbrella term that includes any communication devices, computing hardware, content tools, as well as software applications.

Interdisciplinary Research: Integration of two or more seemingly exclusive academic disciplines or research fields in order to enhance understanding of a research phenomenon or to create new knowledge.

IT Artifact: Bundles of hardware infrastructure, software applications, informational content, and supporting resources that serve specific goals and needs in personal or organizational contexts.

Socio-Technical Perspective: A research outlook that highlights the interdependence and inextricable linkages between people (sociological systems) and ICTs (technological systems), underscores the co-evolution of these systems, and emphasizes that both systems need to be jointly optimized in order to produce positive practical outcomes.

Virtual Communities: (General definition) an aggregation of individuals or organizations with a shared purpose, who interact through a variety of technology platforms including social networks, online discussion forums, blogs, wikis, email lists or newsgroups.

Virtual Communities: (Proposed definition) an aggregation of participants (individuals or organizations) with a shared purpose, who have their interactions mediated through a technology platform and guided by collective protocols, and who embrace a cooperative membership persona in their online interactions.

H

ENDNOTES

- ¹ The highlighted references in Table 2 are based on top ten citations on virtual communities from the ISI Web of Science Citation Index as reported in Laine (2009).
- ² By no means are these the only socio-technical literature domains that discuss virtual communities. Nevertheless, they provide a modest view of cross-functional perspectives related to sociological/psychological and technological attributes of virtual communities.
- ³ The constituents of the proposed definition have deliberately been named using 5Ps. Acronyms might be passé and this particular one may even be cliché, but it provides a short way of describing the essence of the proposed definition.

The Trajectivity of Virtual Worlds

Christophe Duret

Université de Sherbrooke, Canada

INTRODUCTION¹

According to Stéphane Vial (2016), “there is a profane metaphysics that operates at the heart of the contemporary imagination, which postulates that the human world is bisected by an invisible border that separates the so-called real and the so-called virtual” (p. 135).

However no meaning of “virtual” validates this dichotomy, so it would be more appropriate to speak of “digital monism” (Vial, 2014; Stimler & Vial, 2014) to describe the phenomenon of virtual environments, a formulation which “states that the human reality is a digital-centered hybrid environment made of mixed systems and matters constantly interlinked, that tends to form a single continuous multimaterial artifactual substance.” (Stimler & Vial, 2014, para. 4). This profane metaphysics underpins the opposition between cyberspace and ‘meatspace’, borrowed from cyberpunk literature, or between offline and online. This has been widely disseminated by various web commentators, and also by researchers.

This chapter will propose an ontology of virtual worlds that calls into question the dichotomy between the real and the virtual. This will draw on the concepts of trajectivity and *médiance* (Berque, 2000) in order to describe the way virtual worlds, with their technological and symbolic features, take part in the construction of milieus (or “human environments”) (first part: *Background*). This theoretical proposition will be illustrated with the analysis of *Arcadia*, a virtual world built in *Second Life* (second part: *Second Life’s Arcadia as a Virtual World*). Finally, a mesocriticism will be proposed as a new approach for the study of virtual worlds (third part: *Future research directions*).

BACKGROUND

Researches into virtual worlds in the 1990s and 2000s are characterized by their tendency to consider them separate areas from the real world, betraying a perspective Nathan Jurgenson (2012) calls “digital dualism”. As Doel & Clarke (1999) and Latzko-Toth & Proulx (2006) point out, typical of this dualism are the epistemological postures making virtuality a degraded representation of reality or a solution to correct its flaws, the first reflecting a vision of the virtual as a simulacrum (Baudrillard, 1981), the second being put forward by techno-optimist authors such as Howard Rheingold (2000).

“Virtual” is a term whose meaning varies over history and from one researcher to another. In its long history, it has in turn been synonymous with the potential, the artificial and the simulational (Vial, 2014).

The virtual is known primarily as that which exists potentially, as opposed to what exists actually. Thus, in the eighteenth century, the science of mechanics called “virtual realities of the physics” the matrix of possibilities in which the empirical world represents an actualization (Latzko-Toth & Proulx, 2006). Following on from this, the virtual “is nothing other than an ontological regime, a particular way of being real, that which, in short, *exists without manifesting itself*” (Vial, 2014, p. 179, original in italics). Thus, the virtual is real without being actual (Deleuze, 1996; Granger, 1995; Lévy, 1998).

In the field of optics, the virtual is given a second meaning. For the physicists, the virtual image is an image perceived by the eye that comes from an optical instrument, as opposed to the actual

image, which is present on a screen. According to Vial (2014), the term “real” here as opposed to “virtual” is inappropriate, since in both cases they are discernible realities; the virtual image is real, but artificial.

In the field of IT, finally, the virtual becomes ‘simulational’. That is, as in optics, an artificial form, and more specifically, a “process capable, via programming techniques, of simulating a digital behavior *independently* of the physical medium on which (paradoxically) it *depends*” (Vial, 2014, p. 181, original in italics). While the simulacrum is a matter of lies and illusion, points out Vial (2014), simulations are artificially constructed but ontologically real. The virtual is thus equivalent to a computer model. It translates the concept as an idealized version of the modelled object (Latzko-Toth & Proulx, 2006), since it retains from the latter only a few characteristics and behaviors deemed relevant. This implies, as outlined by Gonzalo Frasca (2003) with his concept of simulation rhetoric, that the model conveys the point of view of the author.

The virtual understood as simulational is not unrelated to the term defined by Charles Sanders Peirce (1974). Indeed, according to him “a virtual X (where X is a common noun) is something, not an X, which has the efficiency (virtus) of an X.” (p. 261) In other words, a virtual object (a simulation) produces the same effect as the simulated object without merging with it. This is the case of an Internet forum, for instance, which, like the agora, is a facilitator of debates and discussions. As such, the virtual cannot be equated to ‘potential’ as it is, according to Peirce, “almost its contrary. For the potential X is the nature of X, but is without actual efficiency” (p. 261)

It is from the late 1980s, mentions Vial (2014), that some digital thinkers merge the meanings of the term “virtual” as both simulational and potential. During this era there appeared a profane metaphysics dichotomizing the real and the virtual, that he describes as a form of phenomenological judgment in response to the shock caused by the arrival of digital interfaces in the perceptual hab-

its of individuals (Vial, 2016). This judgment at first led to the idea of a real world separate from a virtual world. But since then, incorporated into daily practices, the new realities that accompanied the digital revolution, (videogames, social media, etc.) have become commonplace. Thus, “by being integrated into our world experience, they create a new phenomenological viewing point by which virtual beings of the digital system can become world phenomena” (Vial, 2014, p. 186), making it now appropriate to speak of “digital monadism” to describe them (Stimler & Vial, 2014). Neal Stimler and Stéphane Vial subscribe, in this sense, to a third epistemological posture, where virtuality is considered a constitutive phenomenon of reality, as “the principle of ‘hybridization’ of the various levels of reality” (Latzko-Toth & Proulx, 2006, p. 58). In the same vein, Don Slater (2002) questioned the offline / online dichotomy and found that “virtuality is clearly not a feature of the media but one social practice of media use amongst many others.” (p. 544) He thus decompartmentalizes the so-called real and the so-called virtual.

Jurgenson (2012) agrees with Slater when he argues that mobile phones and social media – in the context of the Arab Spring, the Occupy movement, and flash mobs – give rise to “massive gatherings of digitally-connected individuals in physical space [where] digital and physical enmesh to form an ‘augmented reality’.” (p. 83). He therefore echoes the position of Beth Coleman (2011), who describes the emergence of an age of mobile, pervasive, networked connectivity. This network society encompasses a multiplicity of network combinations and might be understood as a continuum that crosses the virtual and the real (the online and the offline). Coleman calls this augmented reality “X-reality” and she argues for a new “understanding of networked media as augmentation of self and world” (p. 83).

Maude Bonenfant (2011) and Vili Lehdonvirta (2010) adopt the same epistemological posture as Stimler and Vial and attribute the false real/virtual dichotomy in MMOGs (massively multiplayer online games) to the concept of magic circle

(Huizinga, 1951), this boundary within which the game is circumscribed, considered an activity isolated from everyday life. This concept results in an exceptionalist perspective of videogames considered objects with sealed borders (see Bartle, 2006; Castronova, 2004; Salen & Zimmerman, 2003) that opposes a departicularising perspective of the games considered as an activity in an osmotic relationship with its environment (society, culture, media landscape, etc.) (see Bonenfant, 2011; Boutet, Carvajal, Ter Minassian, & Triclot, 2013; Lehdonvirta, 2010).

Our own research on *Second Life*'s Gorean role-playing games (Duret, 2014, 2015, 2016a,b) belongs to the departicularizing perspective and supports the principle of hybridization. The research shows that players carry out constant displacements between the different levels of the game (virtual world per se, diegesis, formal structure, etc.), applying a multitude of fictional, ludic, social, technical, and symbolic frameworks in order to make sense of their gaming experience. These displacements and the lability of the frameworks (Goffman, 1974) that assure their organization as a gaming experience are explained by the cognitivist concept of attentional resource allocation. This concept affords the users in virtual worlds an understanding of engagement as a phenomenon located both inside and outside the boundaries of the simulation.

The Trajectivity of Virtual Worlds

In this chapter, the term 'virtual' should be read in the sense of 'simulation' (as both a model and efficiency). To prevent the temptation of digital dualism, we will now ontologically base the reality of virtual worlds by regarding them as technical, symbolic, and technosymbolic extensions of the human milieus. Following the principle of hybridization and of digital monism, as seen above, this signifies the consideration of virtual worlds not as entities belonging to a separate sphere or as digital supports for social activities, but as one component of the milieu, which unites within one web the

digital and non-digital relationships, the symbolic and the technical, the subject and the object, the simulation and the simulated phenomenon. To do this, it will be necessary to call on the concepts of *médiance* and trajectivity.

The geographer Augustin Berque (2000) defines the concept of *médiance* as "the relationship of a society to its environment" (p. 128). It refers to the asymmetric ontological structure of human beings that consists of "the bipartition of our being into two unequal 'halves', one invested in the environment through the technical and symbolic, the other made up of our animal body" (p. 128). These halves, "one internal, one external, one physiologically individualized (... our animal body), the other diffused in the milieu (... our '*médial*' body)" (p. 128) indicates a dynamic identity deployed through a process of externalization of functions, which "gradually rejects all the instruments outside of man" (André Leroi-Gourhan, as cited in Berque, 2000, p. 98). These functions formerly belonged to the animal body of the human being. During the course of evolution, the process took the form of a "triple and mutual engendering" (p. 96), composed of hominization (the passage from animals to humans), anthropization (the objectification of things through technique) and humanization (the subjective transformation of things with the aid of symbols). This triple engendering involves the symbolic, technical and ecological in the same bundle of relationships. It constitutes the milieu, and the concept of *médiance* reflects the meaning given to this milieu.

The milieu is neither subjective nor objective, it is trajective. According to Berque (2000), the concept of trajectivity refers to the fact that the reality of the milieu cannot be understood by modern dualism. This reality is neither subjective (from the perspective of a social actor) nor objective. It is the result of a relation called 'trajectivity'. The trajection is the operation through which the subject and the object grow together in order to produce the concrete reality. They are both embedded in a web of relationships that are technical,

symbolic and ecological. These relationships are deployed over time and on a social rather than an individual scale. The human being comes from such relationships, since it is caught in this frame which constitutes its existential web, its milieu.

According to Berque (2000), the human being externalizes ('cosmizes') his animal body in the environment through technique and internalizes (somatizes) the world in this same body through the symbolic. It is through the process of somatization that one represents the world. However, Berque's externalization/internalization dichotomy cannot take into account the numerous devices whose roles are to reduce the symbolic complexity (viewed in terms of data) of the contemporary milieus in order to organize their representation in an accessible manner. Thus, it is a matter of internalizing the symbolic through technique. Therefore, we will describe these tools as 'technosymbolic'. Technosymbolic tools (e.g. geographical information systems, web search engines, mathematical models, etc.) propose a scaling of the complex contemporary milieus within the limits of human cognitive resources in order to prevent any fragmentary somatization (or 'dys-somatization'). In this sense, they serve as auxiliaries in the cognitive mapping (Jameson, 1991; Lynch, 1960) of the milieus. Virtual worlds as computer models constitute technosymbolic tools. Every model retains only a few characteristics from the modelled object. Therefore, virtual worlds reduce the complexity of the modelled milieu and facilitate their internalization when they symbolically illustrate the data and the behaviors that characterize these milieus.

The argument put forward in this section is that virtual worlds, which are simultaneously symbols (3D simulations), techniques (e.g. communication devices, sets of rules), technosymbolic tools, and navigable spaces, occupy a significant place in this bundle of relationships that make up the *milieu*, in the same way as physical places. At the scale of the *milieu*, virtual worlds are as real as are social interactions, rocks or individuals, which suggest a digital monism. As milieus, virtual

worlds proceed from a technical and symbolic deployment of space as well as exceed their *topos* (their objective and measurable physical space). Therefore, virtual worlds belong to the *médial* body. By doing so, they participate along with the ontological structure of the human being. As simulations, virtual worlds possess, for instance, the efficiency of tangibles places of sociability, yet within the mode of telepresence and in a symbolic space. Finally, virtual worlds constitute technosymbolic tools: in addition to technically extending the human milieus and bringing them within the boundaries of the animal body in the form of symbols (somatization), they serve as auxiliaries in the latter process when they carry out a cognitive scaling.

SECOND LIFE'S ARCADIA AS A VIRTUAL WORLD

Basing virtual worlds ontologically on the concepts of trajectory and *médiance* is a first step. The next step will be to show how this foundation is relevant to the analysis of a specific virtual world. This is proposed through a brief analysis of *Second Life's Arcadia*².

Arcadia is a mountainous region of Greece, in the central and eastern part of the Peloponnese peninsula. This mythical landscape banishes urban life and is populated by shepherds. It proposes a "refusal of the social organization and its constraints and it develops around the themes of the simplicity, the nature, and the pastoral way of life" (Letonturier, 2013, pp. 223-224). Arcadia is found in poetry, opera and painting, depicted by poets and artists as famous as Virgil, Ovid, and Nicolas Poussin.-According to Lyman Tower Sargent (1994), it is reminiscent of utopia and according to Françoise Duvignaud (1994), this utopia is characterized by a sense of nostalgia. It feeds the imagination of exiles haunted by nostalgia for an idealized place whose loss is painful.

Now what about the virtual Arcadia? Arcadia is a "sim" built in *Second Life*, a multi-user virtual

environment inhabited by people via their avatar. “Sims” or “simulators” are three-dimensional virtual worlds. They are leased to users who design and administer them.

Arcadia as a virtual world forms, at the same time, a technical extension of human milieus, a symbolic representation of these milieus, and a technosymbolic tool that facilitates their somatization with the support of cognitive scaling.

Arcadia as an Extension of Human Milieus

The externalization of the technique on the environment takes into account the projection of the animal body in the *médial* body, this social part of beings. *Arcadia* encourages this social dimension as a communication and sociability device.

The housing design and the furnishings foster sociability and conviviality. Indeed, there is a profusion of couches, garden furniture, bar counters, tatamis and “zabutons” (Japanese cushions). In addition, the sim proposes places of sociability like terraces, rotundas, a café, a library, a living room, and a sandy beach. The main architectural feature of *Arcadia* is its rotundity (as can be seen in its rooms, terraces, rotundas, bar counters, etc.), which encourages gatherings, requiring that everyone be seen. Communicational devices (text and voice chat, private messaging, scripted nonverbal language of the avatars) also promote sociability. Finally, access to the sim is open to the public, so everyone can access it freely. As with all physical places that engender sociability (restaurants, bars, cafés, etc.), *Arcadia* provides the same efficiency that foster interactions and communication between users.

Arcadia as a Modelization of Human Milieus

Like the mythical Arcadia, *Arcadia* represents a nostalgic utopia. As such, it models an idealized epoch and place that represents a critique of the social conjuncture in which the modeller lives.

The mythical Arcadia consists of a community governed by simple rules and a pastoral way of life. It belongs to a pre-industrial past where human beings, their habitat, and nature live harmoniously together. The way *Arcadia* was modelled testifies to the modeller’s view on the mythical place and, implicitly, of his own epoch, symmetrically deemed as socially complex, overurbanized, overindustrialized, and alienated from nature. In addition, *Arcadia* participates in the internalization of the world: the lost ideal world, but also the contemporary one, which is deemed flawed in comparison with the former.

Arcadia is a simulation of the mythical eponymous landscape and not a reconstruction of the geographical area. It nevertheless retains from the latter a flat landscape surrounded by steep mountains. *Arcadia* is in fact an archipelago surrounded by a mountain range. The flora and fauna of *Arcadia* are heterogeneous. The first combines specimens from temperate zones (e.g., cypresses, pines) and tropical (e.g., palm trees) with border ponds, waterfalls, cliffs and white sandy beaches. The second combines domestic animals (cows, horses, sheep, llamas, fishes in a garden pond, etc.) as well as wildlife (manatees, dromedaries, flamingos, deers, weasels, etc.): the fertile Arcadia of the shepherds meets the pristine wilderness of the unspoiled islands. This heterogeneity suggests an idealization of nature: it is not an ecosystem that is simulated, but nature itself, thereby returning to an Arcadia viewed as a “fantastical mental landscape” (Duvignaud, 1994, p. 52).

Human dwellings (terraces, winter gardens, café) are not absent from the sim, but they intermingle intimately and harmoniously with nature, effectively forming open architectures endowed with green roofs and within which grows vegetation.

All signs related to urbanization and industrialization are absent from *Arcadia*. On the one hand, it offers landscapes and a habitat on a human scale, as opposed to cityscapes and metropolises which are problematic to map cognitively (Lynch, 1960). On the other hand, there is a total absence

of production. *Arcadia* offers itself as a place of leisure, sociability, and relaxation. The presence of domestic animals coupled with the absence of work suggests the idea of *Arcadia* as a nourishing earth, “the idea of a ‘nature’ that would see humans released from work” (Duvignaud, 1994, p. 52).

So far, the interlacing of relationships of the milieu (its trajectory) is composed of technical (*Second Life* software allowing the design and management of the environment, servers, computers, communication devices, etc.) and symbolic (*Arcadia* as nostalgic utopia) constituents. *Arcadia* therefore combines trajectively both the subjective – symbolic representations of the world and social actors – and the objective – material support consisting of telecommunications networks, servers and computers, as well as the reference objects used in the design of *Arcadia* (beaches, furnishings, mountain ranges, flora and fauna, etc.). The sim also involves a community (the designer and the owner of *Arcadia*, *Second Life* employees, authors who have developed works by taking up and augmenting the *Arcadia* theme, users who explore the sim, socialising and forming a community within it, etc.). In addition, *Arcadia* involves several time frames: the plury-millennial arcadian conventions in art, the multi-centennial traditions of the utopian genre, and the preindustrial and contemporary epochs involved (positively or negatively) by the arcadian utopia. Let’s now see the technosymbolic dimension of *Arcadia*.

Arcadia as a Technosymbolic Device

Along with efficiency, technosymbolicity constitutes another aspect of virtual worlds taken as simulations. *Arcadia* fulfills the role of auxiliary in the somatization of the world when it models it on a small scale. In terms borrowed from Kevin Lynch (1960) and Fredric Jameson (1991), the sim helps its users to cognitively map the world in which they live (the city for the former, the global socioeconomic system of the late-capitalism for the latter). Without mapping ability, this world would appear alienating because it would be too complex to be understood globally.

As a simulation, *Arcadia* takes place on a small scale. In *Second Life*, a sim has a size of 65 536 sqm and only 100 avatars are admitted there simultaneously. *Arcadia* is thus an easy place to cognitively map the technical, symbolic and social levels. Arcadian utopia and the contemporary world are both summoned in this restricted place. The contemporary world is summoned on one hand as non-reference (it exists negatively as a set of flaws to avoid) and on the other through the form of vending machines that inscribe the contemporary intangible economy at the heart of the arcadian utopia. Indeed, vending machines are scattered across the archipelago of *Second Life* in the form of a network that notably includes *Arcadia*. This network can be seen as an atopia (a non-place). Non-places are defined by Marc Augé (1992) as non-identity, non-relational and non-historical places. They are representative of a system that promotes the free movement of men, goods and information flows. Airports, highways, malls and communication networks are representative of non-places. Vending machines allow the sale of artifacts in the sims. They require payment in *Linden* dollars, the currency of *Second Life* convertible into US currency. *Arcadia* offers the sale of miscellaneous objects (folding screens, tatamis, cushions, mobile storage cabinetries, bikinis, DJ mixers, speakers, turntables, etc.) through a set of vending machines tied into the wider networks of *Second Life* and of the intangible economy. Like the communication devices above-mentioned, these virtual vending machines have efficiency (the efficiency of physical stores. Because of these vending machines, the sim is both closed (utopian) and open (as an atopic network connected to the intangible economy) and it transposes a global-scale phenomenon into a local scale.

Additionally, as a technosymbolic tool, *Arcadia* summarizes the problematic state of contemporary *médiance*, translated by the need for nature, a desire felt by human beings to return to an environment of natural living (Bailly & Bourdeau-Lepage, 2011). It is a symptom of what Berque (2000) describes as the decosmization of modernity whereby nature

and things are transformed in systems of objects, and through which the individual is artificially separated from his milieu.

As we have seen previously, *Arcadia* simulates a world in which nature and human habitats intertwine. This utopian relationship reflects a “structural need for unspoiled nature” (Berque 2000, p. 155). The distinction between natural and artificial tends to disappear in this enclave where an attempt to reinscribe the individual in his milieu (a recosmization) is at stake. The vending machines decompartmentalize the arcadian enclave in reconnecting it to the atopic networks of the intangible economy, a presence of a hypertrophied technique at the heart of the *médial* body.

FUTURE RESEARCH DIRECTIONS

Replacing virtual worlds in their milieu overcomes the digital dualism and draws attention to their eco-symbolic-technical dimensions, which are collective and extend through a plurality of time frames. Such an approach could be qualified as a hermeneutics of virtual worlds, a *mesocriticism* (the “meso” prefix here representing “milieu”) capable of uncovering the web of relationships without which a virtual object is nothing more than a meaningless assemblage of pixels, rules, and hardware. The analysis of *Arcadia* is only a draft of this mesocriticism and calls for the development of new methodological tools. Furthermore, when these virtual worlds are games, they come with an extra dimension: a diegesis (the fictional spatiotemporal universe of the game), which the mesocriticism must take into account in future researches.

CONCLUSION

Thinking of the virtual in the context of a bipartition between animal body and *médial* body permits its inclusion in the same ontological definition of the human being, since it becomes one technical,

symbolic, and technosymbolic tool among others whereby the latter invests himself in his milieu and makes sense of it. This conception avoids the false real/virtual dichotomy and hybrids the various levels of the milieu in a trajective reality. In addition, viewing the virtual as a simulation allows us to link together its characteristics that are efficiency and modelling. According to these qualities, virtual worlds constitute communication, selling, and cognitive scaling tools. Finally, the analysis of *Arcadia* as virtual world highlights its paradoxical nature: as a construction both utopian and nostalgic, it provides refuge for anyone who aspires to a return to nature, but without to avoid a technically and symbolically hypertrophied *médial* body: after all, *Arcadia* stays the avatar of an intangible economy. Its inclusion in the economic sphere of *Second Life* gives it the quality of utopias that Jameson (2005) calls “postmodern”, these “islands in the net, a constellation of discontinuous centers, themselves internally decentered” (p. 221). In this sense, *Arcadia* can be compared to contemporary concrete utopias such as Ecofaubourg® (2008), which offers *a new form of city that is more and more conscious of sustainable development and seeks to reconcile urban lifestyles and economic dynamism with environmental conservation* [which is] *structured around various kinds of network... [as its aims are] to be mobile, connected and service-oriented.* (para. 1)

This analysis depicts a technosymbolically constructs diagram of a contemporary milieu in which even the most isolated islands remain connected on a global scale.

KEY TERMS AND DEFINITIONS

Médiance: The meaning given to the milieu (see Milieu).

Milieu: (Or “human environment”) is the interlacing of the symbolic, technical and ecological in the same bundle of relationships. The milieu is a trajectory reality (see Trajection/trajectivity).

Non-Places: Non-identity, non-relational and non-historical places. Representative of a system that promotes the free movement of men, goods and information flows (e.g. airports, highways, malls and communication networks).

Sims: Three-dimensional virtual worlds built in Second Life.

Trajection/Trajectivity: The trajectory is the dynamics through which the subject and

the object grow together in order to produce the concrete reality. They are both embedded in a web of relationships that are technical, symbolic and ecological. The quality of this dynamics is called trajectivity.

Virtual Hoarding

Jo Ann Oravec

University of Wisconsin – Whitewater, USA

INTRODUCTION

This article outlines hoarding issues involving virtual goods (including databases, videos, images, and digital documents) in workplace, household, and personal contexts. It covers security issues, intellectual property concerns, and matters related to information flow in organizational settings. The article also includes reflections about the moral and personal dimensions of virtual hoarding, with an emphasis on information ethics and the opportunistic appropriation of organizational data (and in some cases, knowledge) for individual gain. Organizations as well as individuals could face substantial losses through the compulsion to “save” virtual goods without developing and carrying out appropriate strategies for managing them.

Virtual hoarding issues may not seem to be critical given the decreased costs of on-site and backup storage as well as relatively-inexpensive storage facilities in the “cloud.” However, data that are not managed in terms of their formats and their storage substrata could certainly present issues for organizations; also, data that are inappropriately removed from the flow of information in organizations may put vital processes at risk. On the level of the individual, personal and professional issues involving the storage of hundreds of thousands of images, videos, and documents with little context or metadata could present comparable problems, albeit on a more contained scale. According to researchers, the reasons that individuals become hoarders range from uncertainty avoidance and OCD (obsessive-compulsive disorder) to opportunistic motives for personal acquisition and perhaps subsequent advancement (Bratotiis, Schmalisch, & Steketee, 2011; Grant, 2014; Oravec, 2015). At the organizational level, the system-level aspects

that lead individuals in particular contexts to hoard data may have close parallels to these individual-level phenomena.

BACKGROUND

The study of virtual or digital hoarding is just emerging, and new case studies, survey results, and other forms of research are being undertaken and disseminated (Oravec, 2015; van Bennekom, Blom, Vulink, & Denys, 2015). Although this article focuses on the hoarding of virtual goods, some discussion of the hoarding of physical objects may provide background and insights. In a variety of social settings, hoarding behavior involving physical items is expanding in its impact; hoarding has been construed as a mental health issue in some organizations (Bratotiis, Schmalisch, & Steketee, 2011) and has been labeled as a disorder in the DSM-5 (*Diagnostic and Statistical Manual of Mental Disorders*, American Psychiatric Association, 2013). Capacities for managing the locations of and access to physical as well as virtual entities are often considered central to competent societal functioning. Lepselter (2011) relates dozens of negative characterizations of hoarding in newspapers, television, and social media. The hoarding of “virtual goods” is also generating concern and has the potential to be even more costly for organizations than its physical correlate. Files that are not properly identified and stored might be seen as appropriately “saved” if placed in the “cloud.” However, if metadata about the files are not available, the files may be essentially worthless, wasting precious organizational resources. Gormley and Gormley (2012) describe the condition of “information clutter” as running

DOI: 10.4018/978-1-5225-2255-3.ch373

parallel with hoarding behavior, a situation that is generally not conducive to conducting efficient workplace operations.

Certain kinds of organizations and professions may be more prone to virtual hoarding issues than others. Peyton (2015) describes the problems some law firms have with digital data management and relates that “Many firms are notorious data hoarders and seem to hold old records without any legitimate justification” (p. 18). Knowledge hoarding has been shown to become a concern in workplace contexts in which uncertainty and loss of trust are issues (Holten, Hancock, Persson, Hansen, & Hogh, 2016; Oravec, 2017). For many professionals, the transition is often difficult from an era in which information was relatively scarce (just a few decades ago) to one in which information resources are overwhelming in size, access, and complexity. Peyton relates that “sub-standard information governance and recordkeeping model” are often found in professional settings, and declares that “Legitimate business justifications for retaining electronic information do not include ‘I may need that information someday—you never know’” (p. 19). “Big data” analytic capabilities may compensate for some non-optimal organizational storage and retrieval practices, but may not provide an adequate overall solution for archival problems (Datskovsky, 2013).

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

The varieties of virtual goods accumulated by individuals have evolved from simple e-mail address rosters to complex fantasy sports strategies and extraordinarily detailed avatars (Ng and Höpfl, 2011; Oravec, 2015). Good (2013) categorizes an assortment of the “personal media archives” that are often collected and maintained by households, assemblages that include digital images associated with vacations and other family events. Some social media platforms have served to support hoard-

ing behavior in archival activities: for example, Schiele and Hughes (2013) describe hoarding behavior linked with the Pinterest platform, relating how the accumulation of thousands of images becomes part of everyday life in many households. They assert that “consumers lead second lives online claiming ownership to virtual goods and images, using social media to create, control and consume content” (p. 47). In the 1990s, the emergence of the music sharing program Napster brought considerable attention to the hoarding of digital entities, with an emphasis on intellectual property concerns (Newman, 2013). BitTorrent and other kinds of peer-to-peer networks helped to create a “sharing culture” in which hoarding of virtual goods without subsequently allowing others to download them was often portrayed as inappropriate and even “selfish” behavior. The “hoarding ratios” were high for those who accumulated digital materials from the network without making them subsequently available to others (Rando, 2014).

The hoarding of virtual items has not yet been shown to be a direct substitute in psychological terms for the hoarding of physical items. Researchers have provided few clues as to whether the individuals who collect massive quantities of physical goods will have tendencies to collect large amounts of virtual goods as well. So far, little research has been done linking the two and asking whether hoarders in physical realms have tendencies to hoard in virtual platforms as well (Oravec, 2015). Hogan (2015) describes a perspective that may shed light on virtual hoarding phenomena: “the more we encourage the mass hoarding of digital media based on this dumpster model, the more we reinforce the logic of the always-on, always-ready archive” (p. 20). The casualness with which large data repositories can be stored without strategic consideration of how or whether they will be accessed in the future can make individuals feel temporary security; after all, they did not delete the files so they supposedly will be able to access them at a later point, even if the forensics involved (or the excavation, in terms of massive

hoarding) would be expensive. Some of these data resources can subsequently be subpoenaed as part of legal claims concerning various items or services provided by organizations.

Concerns about hoarding are serving to bridge the physical and virtual realms; for instance, St-Pierre-Delorme & O'Connor (2016) developed virtual reality spaces that simulate personal hoarding settings in order to destigmatize the manipulation and storage of physical household objects. From a related perspective, there are some promising prospects for somehow displacing the hoarding of printed photographs and related materials with the accumulation of digital files (switching to the hoarding of digital videos rather than bulky tapes, etc.), in hopes that the virtual items can acquire comparable sentimental linkages to significant personal experiences. Many young people have collected tens of thousands of digital files with music and video content, possibly freeing a great deal of shelf space while maintaining some semblance of personal attachment to the enterprise. Digital music has become a commodity that "opens up greater opportunities for surveillance, advertising, consumption and technological interference" (Morris, 2010, p. 4). Denegri-Knott, Watkins, and Wood (2012) refer to some of these mass accumulation efforts as "stockpiling," which captures some of the lack of selectivity in many virtual compilations. In contrast, Kibby (2009) describes how the acts of accessing, tagging, and storing digital music files can instill meaning into these virtual objects and turn the files into a "collection" rather than just a hoard (p. 428). Sinn and Syn (2014) describe how Facebook became a part of some users' "personal documentation" and digital storage systems, affording a means for them to structure various household archival traces and records. Financial instruments and records in both digital and physical forms can be hoarded, often endangering household finances (Canale & Klontz, 2013).

Workplace settings can raise an assortment of related concerns about the hoarding of virtual entities, including social and ethical issues involving

opportunistic hoarding. Gormley and Gormley (2012) discuss how data hoarding is manifested in employee behavior, stating that "hoarding data can create a false sense of uncertainty avoidance" (p. 90) as individuals accumulate, but do not process and share, organizational information. Some of these hoarding activities can be strategic as individuals retain information that would otherwise be part of regular organization "information flow" for opportunistic reasons. Wiewiora, Trigunarsyah, Murphy, and Coffey (2013) present research on potential organizational culture influences in the levels of sharing versus hoarding in which workplace participants engage. Many organizations do not have clear policies concerning data management; distinctions can be difficult between what is retained because of organizational needs and what is "hoarded" ("Is It Workplace Hoarding," 2014). Managements often view the orderliness of the physical and virtual assets of their organizations to be of high value (Kim, 2014), so hoarding behavior related to virtual goods of various sorts may continue to be of concern. Best practices at the organizational level concerning deletion of unneeded data and other approaches can be of benefit in providing current or potential hoarders with some guidance (van Bussel, Smit, & van de Pas, 2015).

SOLUTIONS AND RECOMMENDATIONS

Some of the strategies that are being examined for the identification and treatment of physical hoarding behaviors may have parallels in virtual realms. *The Hoarding Handbook* (Bratotiis, Schmalisch, & Steketee, 2011) describes an assortment of programs for mitigating hoarding-related problems, some of which are online. Research is also needed on the difficult issue of whether or how to redesign environments so as to accommodate individuals who exhibit hoarding behavior. Labeling hoarders as "disabled" could be problematic in many organizational contexts,

entailing expenditures for counseling and perhaps also the redesign of some spaces (including virtual spaces) and related tasks. In the workplace, the hoarding of pornographic images in organization-owned computers and online networks has also continued; it is especially problematic because of the fact that the individuals involved could readily download and store the materials on their own digital devices (Oravec, 2012). As the demands for disposition of increasing numbers and varieties of virtual items expands, the phenomenon of hoarding is expanding, both in its organizational and personal manifestations. Providing basic support and empowerment for individuals in organizations is part of establishing a just society. Designing workplace environments in which the management of virtual goods can be performed in a less overwhelming, more humane, and less time-consumptive way can aid organizations and communities as well as individuals.

Mayer-Schönberger (2010) outlines some of the “virtues” of data deletion in our current, information-saturated society, including the forgetting of irrelevant and out-of-date information. However, some virtual hoarding behaviors and tendencies may indeed have positive aspects as some individuals in organizations inadvertently retain important communications, images, or documents that are later determined to be of importance. Hoardings can preserve various organizational traces and virtual entities in a relatively-unadulterated “time capsule” (Oravec, 2013). Unearthing these vital virtual entities could be difficult in a hoarding-related system, however, and efforts akin to “data fracking” may be required (Gray & Alles, 2015). Generational differences may also emerge as salient in understanding hoarding behavior and perhaps using these tendencies to best organizational advantage: for example, individuals who hoarded thousands of music files with the Napster platform in the 1990s may have different orientations toward the retaining of virtual goods than many of the individuals who managed personal collections of vinyl albums in the 1960s and 70s.

Marginal accumulation of virtual goods (such as digital documents and musical or video files) has been construed as having fairly little physical impact on the planet (Fried, 2014), except for the problems involved with the production of computing equipment and electricity, which can produce considerable levels of toxicity. Once the basic equipment is manufactured and placed in a secure, temperature-controlled environment, additional virtual goods can be added with little environmental damage. For example, social media users who hoard increasing numbers of friends on Facebook, often without knowing the individuals involved, may be considered as engaging in “hoarding” yet little damage is done to the planet’s ecosystem. In contrast, many varieties of hoarding of physical goods present substantial environmental and public health challenges, such as in the hoarding of pets or perishable food items. In terms of its physical footprint, the collections of images and videos that can be placed even on an inexpensive digital device can dwarf a comparable assortment of canvas, print, or film renditions. However, the hoarding of virtual materials can have other overall negative impacts on society, including potential intellectual property violations.

H

FUTURE RESEARCH DIRECTIONS

For individuals whose hoarding behavior has some linkages to concerns about memory losses (and their related anxieties), the continuous digital recording of everyday events may eventually provide some relief. Some individuals are already engaged in experiments in which their entire lives are being taped (“lifelogging”) so that any slippage in memory could be compensated (Gurrin, Smeaton, & Doherty, 2014). Many professionals, managers, and educators already have a great deal of their effort made “transparent” with extensive documentation, blogging, and surveillance (Oravec, 2004). Perhaps these dramatic ways of supplementing and even enhancing one’s memory will eventually serve to alter some of the dysfunctional

patterns that lead to hoarding, although they may result in different varieties of hoarding syndromes. The growing assortment of forms of “ephemeral communications” (messages that are intended to be received and subsequently disappear) can also present alternative perspectives on the perceived need to hoard digital materials. These genres of communications are supported in Snapchat and comparable messaging platforms (Ganzemuller, 2014). Future research will explore how individuals who need help dealing with virtual hoarding issues can call for help most effectively, in ways comparable to the requests for assistance of physical-good hoarders (Bratiotis, Davidow, Glossner, & Steketee, 2016).

Increasing attention is being directed to the hoarding of dark data and the dangers of indiscriminate storage of files that could possibly harbor dangerous security hazards. The term “dark data” is often used to refer to a database’s content that is “not carefully indexed and stored so it becomes nearly invisible to scientists and other potential users and therefore is more likely to remain underutilized and eventually lost” (Heidorn, 2008, p. 280; Douglass, Allard, Tenopir, Wu, & Frame, 2014). The Internet of Things (IoT) may produce even more opportunities for the production of dark data and their potential hoarding:

Every device will, in the future, be a possible Smart Component on the Internet. Many everyday devices already have a computer chip in them that people do not realize, which if connected to the Internet can start broadcasting or receiving information, either to each other (Machine to Machine or M2M) or to various collection or aggregation points. (Watson, 2015, p. 212)

With the advent of the IoT comes a dramatic increase in the numbers and kinds of devices that have storage capabilities with personal, household, or workplace data. Remote wiping and deletion have already acquired an assortment of mundane applications in deleting such data if these devices are lost or stolen (data that perhaps should have

been deleted long ago in regular information management protocols). For example, when individuals lose smartphones and tablets (or as these devices are stolen) deletion of their files can lessen the severity of the loss. Remote wiping and deletion could indeed be used in systems design to mitigate system problems involving hoarding; it has already been used in copyright-related cases. For instance, in 2009, the book *1984* by George Orwell (1950) was removed from some Kindle devices without the direct consent of the device owners, reportedly for copyright concerns (Van Tassel, 2011; Chan, 2012). Entities other than the immediate owner of an artifact can often update, alter, or delete its localized files; this may lessen the potential for stores of suspicious data in specific IoT artifacts, mobile devices, or other networked entity to endanger the overall systems in which they are embedded.

CONCLUSION

Virtual hoarding behaviors can illuminate a number of issues related to data retention and dissemination in organizational settings and personal life. Relatively few individuals go to extremes, jeopardizing their livelihoods and social lives in the organizational or personal hoarding of data. However, the behaviors of a number of individuals in avoiding the application of standard organizational archiving practices can lead to larger cumulative losses for organizations. From the household and personal perspective, ignoring copyright and choosing to accumulate many thousands of files may serve to erode some of the social supports for the information economy and the funding of creative artists (Newman, 2013). Insights from hoarding of physical goods may help us to understand what is involved in the hoarding of virtual goods. Preston, Kringelbach, Knutson, and Whybrow (2014) propose an “interdisciplinary science of consumption” to develop and conduct research on some of these potential insights and interactions.

Framing cloud services and organizational data archives as kinds of “dumpsters” (Hogan, 2015), ones that can be easily searched or readily discarded, can present damaging prospects for organizations. In order to retain their optimal usefulness, data sources require adequate metadata as well as continuing management and oversight. Many individuals have hoarding tendencies and can emphasize with the “pack rat” syndrome, but such behaviors in workplace contexts can be deleterious to the organization in an assortment of dimensions.

KEY TERMS AND DEFINITIONS

Dark Data: Data that are currently inaccessible or unusable by researchers and users (Heidorn, 2008). Data can be “dark” if they are not stored in appropriate ways or provided with metadata or context.

Ephemeral Communications: Communications that are deleted or otherwise not made available after a certain, relatively-short time period; the Internet messaging application Snapchat provides a platform for such interactions.

Information Flow: The circulation of information between and among various entities and individuals. In organizational contexts, information flow can be blocked if individuals hoard information rather than distributing it when needed.

Intellectual Property: Many kinds of virtual entities have financial and productive value; intellectual property considerations structure how these entities are owned and/or controlled by individuals and organizations for certain periods of time. Intellectual property can include copyrights, trademarks, and patents.

OCD: Obsessive-compulsive disorder: A “common, disabling psychiatric disorder characterized by intrusive and unwanted thoughts, images, or urges that cause distress or anxiety and repetitive thoughts or actions” (Grant, 2014, p. 646). It has been linked to some forms of hoarding behavior.

Remote Deletion (or “Remote Wiping”):

Deletion of digital material from a device or artifact (through a networked connection) without direct physical possession of the device or artifact. This procedure can be used to remove potentially-sensitive material from a stolen phone; it can also be used to delete problematic or suspicious files from an Internet of Things (IoT) device.

Virtual Goods: These are non-physical items that are instantiated in some physical and/or electronic media. Virtual goods are often associated with specific intellectual property categories and values (see “Intellectual Property” above).

Cyberloafing and Constructive Recreation

Jo Ann Oravec

University of Wisconsin – Whitewater, USA

INTRODUCTION

“Cyberloafing” in workplace and educational contexts refers to the uses of computer-related applications and devices in ways or at times that are not directly sanctioned by employers, managers, or teachers. It has often been considered as a kind of “time theft” on the part of employees and students (as described in Block, 2001), possibly decreasing workplace and educational productivity by consuming attention, energies, and resources designated for organizational operations. In contrast, many employees and students have construed cyberloafing as a stress reliever and as a support for personal wellbeing, often with the rationale that they are able to engage effectively in alternating or multitasking between and among their various work and off-work endeavors (Adler & Benbunan-Fich, 2013). “Constructive recreation,” in contrast with cyberloafing, comprises online recreation and gamification initiatives that are designed by employees along with managers; these initiatives are designed to be in synch with productive efforts and support the wellbeing of all organizational participants (Oravec, 2002; 2004a). This article compares and contrasts cyberloafing processes with constructive recreation approaches, the latter involving conscientious consideration of how online leisure activities can enhance workplace and educational activity and improve organizational productivity. The article analyzes some current research trends and public discourse related to cyberloafing; it also describes some constructive recreation approaches that have been explored over the past decades.

Many recent computing technology and gamification advances have helped to blur the conceptual and pragmatic boundaries between

“work” and “play,” distinctions that have great cultural variation (Deterding, Dixon, Khaled, & Nacke, 2011; Oravec, 2015). This article indeed focuses on cyberloafing issues within the US and UK, but international dimensions can also become especially salient in a world of globalized corporate interactions and relations. Cyberloafing practices that are acceptable in one nation may be seen in harsher lights in other places, given cultural and ethical differences that affect how work is structured and evaluated (Cheng, Li, Zhai, & Smyth, 2014; Sheikh, Atashgah, & Adibzadegan, 2015). International and regional variations in organizational approaches to cyberloafing can illuminate other significant aspects of workplace culture (Canaan Messarra, Karkoularian, & McCarthy, 2011), variations that can become salient as many organizations deal with international outsourcers or with units that are rooted in various nations.

BACKGROUND

The term “cyberloafing” emerged in academic and popular discourse in the 1990s as a way of characterizing the growing phenomenon of non-sanctioned online recreation and other activities (Oravec, 2002). Cyberloafing has been defined by Lim (2002) as the “act of employees using their companies’ internet access for personal purposes during work hours” (p. 675). Researchers have generated associated concepts such as Anandaraman, Simmers, and D’Ovidio’s (2011) framing of “personal web usage” or PWR, which is a more specific characterization of cyberloafing activity. As outlined in the “Key Words and Definitions” section below, “cyberbludging” is often used in some nations to refer to individuals’ use of comput-

DOI: 10.4018/978-1-5225-2255-3.ch374

ers in the workplace for recreation while shirking responsibility for work outcomes (Hernandez-Castro, 2016; Liaskos & Sandy, 2004). An alternate term, “cyberslacking,” is often used to label computer usage by students or younger members of the workforce (although it sometimes also emerges in broader discussions of the issue). Other characterizations of these phenomena include “non-work-related computing, cyber deviance, personal use at work, Internet abuse, workplace Internet leisure browsing, and junk computing” (Vitak, Crouse, & LaRose, 2011, p. 1751). Cyberloafing has also been examined as an aspect of the larger construct of “counterproductive workplace behavior” (as formulated in O’Neill, Hambley, and Bercovich, 2014), which also refers to a broader assortment of online workplace dysfunctions such as hacking, manipulation of metrics, and theft of resources (Oravec, 2017). Burnay, Billieux, Blairy, & Larøi (2015) linked some forms of cyberloafing with “obsessive passion” (p. 28). Askew (2012) explores the relationship between cyberloafing and task performance, and Jia, Jia, and Karau (2013) examines the influences of personality and workplace situational factors on cyberloafing. Some researchers portray cyberloafing as a kind of “deviance” (Weatherbee, 2010), despite the wide proliferation of cyberloafing behaviors and their normalization in some settings.

Propositions that employees or students should be forced to focus only on their assigned tasks and not be able to take reasonable discretionary breaks run counter to a great deal of managerial, psychological, and educational research (Lim, 2002; Oravec, 1996). For many decades, social scientists have given support to the assumption that human beings generally require some sort of periodic relief and refreshment as they pursue their workplace and educational endeavors (Metcalf, 1952; Souter, 1940). However, the open access that many employees and students have to computer devices and networking has often set up “contested spaces” in a number of workplaces and schools (Oravec, 2004a); these contestations refer to disputes and confrontations over the right to be

able to define what kinds of diversions and times for recreational activity are deemed as acceptable in the workplace or educational institution.

Cyberloafing issues have changed dramatically in character over the decades. When organizational computer resources were very expensive and tightly controlled (in the 1950s through the early 1970s), informal and unregulated access by employees and students was not considered an issue of widespread importance. Only a relatively few individuals were able to explore the uses of computing technology for recreation in the workplace, although their surreptitious initiatives ultimately resulted in some of the early popular video games (Wolf, 2001). Since the 1970s and the advent of the desktop personal computer (PC), however, opportunities for the non-sanctioned use of computers and networking resources expanded dramatically. Employees could access video games on their desks at work as well as engage in computer network interaction in early electronic bulletin boards or listservs (Oravec, 1996). They could also compose their resumes and cover letters during work breaks and produce them on their employers’ printers for a professional-looking product. The “boss key” or “boss button” became a feature on many applications, giving employees an easy way to appear to be working hard on an organizationally-sanctioned application while engaging in unsanctioned efforts (van Gelder, 1982); by pressing a certain key, usually a function key, the PC’s screen would change to a spreadsheet or other business-oriented image. In that era, managers and administrators at nearly all levels of organizational functioning were faced with the prospect that some of their employees could be utilizing computer technology on company time, possibly consuming expensive organizational resources as well. Cyberloafing provided a wake-up call to managers about the power of computer technology to change everyday organizational functioning, often in complex and dysfunctional ways.

Many of the pioneering research and policy initiatives involving cyberloafing were formulated

well before the advent of ubiquitous social media (such as Facebook and Twitter); some approaches still embody the model of the solitary individual who is involved in cyberloafing by interacting with a particular computer application or online resource rather than using computing to extend and enhance group and community interaction (Oravec, 2002). Social media have expanded the range and amount of cyberloafing activity; it has expanded into more of a communal experience and has linked employees for the sharing of pictures, texts, and videos while at work. For example, through Facebook, Twitter, and YouTube, individuals could engage with each other in workplaces and schools, often creating “virtual breakrooms” or “cyber watercoolers” that stretched across organizational settings. In the past decades in Silicon Valley, employees who devoted many hours online to their intense and demanding jobs developed an assortment of innovative ways to spend their available free time online without straying too far from their workplace settings (Tapia, 2004). Other iterations of cyberloafing have also become more intensely personal and intimate as individuals use their wearable technologies to monitor their medical conditions and enhance their personal experiences while on the job.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

Research disciplines that have focused on cyberloafing issues have ranged from information technology and security (as demonstrated by Glassman, Prosch, & Shao, 2015), organizational behavior and leadership studies (Lim, 2002; Jia, Jia, & Karau, 2013), psychology (Wagner *et al.*, 2012), public administration (Hernandez-Castro, 2016; Ozler & Polat, 2012), human resources (Weatherbee, 2010), education (Taneja, Fiore, & Fischer, 2015), and business ethics (Block, 2011). The emerging interdisciplinary field of “cyberpsychology” also developed as a vehicle for studying

cyberloafing and other emerging computer-related phenomena (Anandarajan, Simmers, & D’Ovidio, 2011; Oravec, 2015). With this broad range of research directions and approaches, sometimes confusing amalgams of portraits of cyberloafing phenomena have emerged. From a negative perspective, researchers from various nations have documented billions of lost dollars of productivity over the past decades because of uses of computers in the workplace for non-sanctioned activity (Sheikh, Atashgah, & Adibzadegan, 2015). The opportunity costs involved with cyberloafing are often not included in these estimates; they are difficult to figure as employees and students direct their creative energies toward recreational computer applications other than those relevant for work or school. Blanchard and Henle (2008) distinguish between “minor” cyberloafing (which includes sending and receiving personal email) and “serious” cyberloafing (which includes online gambling as well as interacting with adult-oriented chatrooms and websites). Since the 2000s, “sexting” was identified as a major workplace and school concern, with many cases of managers, employees, and students spending time online during work hours sending or accessing sexually-suggestive messages via computer or phone (Oravec, 2012). Sexting, along with other kinds of serious cyberloafing, engendered legal as well as moral worries for business and educational institutions.

An example of how pervasive and influential cyberloafing can become in organizations involves online shopping. In the early days of the proliferation of the Internet, some kinds of commerce-related cyberloafing were overlooked by managers because they wanted employees to become comfortable with online access and perhaps even obtain useful health or other services online (Belanger & Van Slyke, 2002; Oravec, 2001). Phenomena emerged such as “cyber Monday” (the Monday morning after the popular US post-Thanksgiving shopping day “Black Friday”) in which employees often openly engaged in online shopping with the aid of the computing power

they had on their desks at work, technological access that was often greater than that available at home (Swilley & Goldsmith, 2013). Many online shopping initiatives were indeed conducted with workplace technology rather than home computers because of the increased bandwidth provided in workplace settings. However, as home computing and smartphones proliferated, the need for accommodating such workplace experimentation with computing lessened dramatically. Many employees and managers acquired computer skills at home with the increasingly-inexpensive home and mobile computing technologies, often inspired or driven by their children and friends. Employer tolerance for cyberloafing subsequently diminished in many organizations (Oravec, 2002).

Students using laptops, smartphones, and related devices have ready access to cyberloafing opportunities; restricting the use of these devices has been very difficult in schools and higher education since computers are closely integrated into a great deal of classroom activities. Even if schools install surveillance software on their computer systems, students can use smartphone and smartwatches for non-sanctioned classroom activity. In educational settings, cyberloafing can distract students from maintaining their attention on the teachers' or their peers' presentations during class time, possibly disabling their efforts to achieve their overall educational goals (Taneja, Fiore, & Fischer, 2015). The stress-relieving functions of cyberloafing for students may provide a way for them to remain physically present in a classroom setting while being virtually present elsewhere. Unauthorized use of computing in education is not restricted to students: McBride, Milligan, and Nichols (2013) explored cyberloafing activities among teachers who engaged in non-sanctioned activity while on the job. Education-related issues also involve the engagement of employees in educational activities while at work in circumstances in which their attention is expected to be directed at non-educational tasks. It may seem odd to label educational activities in terms of "loafing," but online educational activities may distract or inter-

fere with critical workplace functions at certain times, possibly leading to workplace mistakes or accidents.

A major issue involving cyberloafing is that of the control and direction of unscheduled and unauthorized computer uses. Many employers, managers, and administrators recognize the importance of stress relief in workplaces and educational institutions. However, many workplace participants are concerned when the organization and not the individual or group determines what computer-enhanced recreation opportunities would be allowed (Belanger & Van Slyke, 2002). The discretionary aspects of cyberloafing have become even more complex as employees and students use their own devices to engage in everyday organizational online interaction, thus often placing themselves outside of the direct surveillance of employers and teachers. The feelings of entitlement to access one's own smartphone or laptop at work can play a role in how cyberloafing behaviors are construed by the parties involved. Individuals have indeed used personal electronics from Sony Walkmans to the latest wearable technologies for decades to provide needed stimulation or relaxation in work environments. However, with the increased cognitive demands involved with many computer applications, new varieties of organizational productivity and safety issues have emerged as individuals attempt to divide their attentions between their engrossing, immersive personal activities and their organization-sanctioned projects. Individual differences are a factor here: some people may indeed be incapable of managing the increased cognitive demands involved with task-break alternation and multitasking while others may be quite comfortable and even improve their performance with the additional stimuli (Adler & Benbunan-Fich, 2013).

Certain aspects of cyberloafing can expose organizations to legal dangers if allowed to continue unchecked. For example, employees and students may access online materials on the job or during class hours that are expressly forbidden in work environments or in society as a whole,

including child pornography or certain forms of illegal gambling. If organizations develop and disseminate clear policies on such problematic access these legal and ethical issues will not be completely solved but at least proactive steps can be taken to address them (Oravec, 2002). Research studies by Ugrin and Pearson (2013) show that “threats, termination, and detection mechanisms are effective deterrents against activities like viewing pornography”(p. 812) but can be less effective toward mitigating some other kinds of cyberloafing (such as personal emailing and social networking).

SOLUTIONS AND RECOMMENDATIONS

Cyberloafing activities can provide useful signals to employers, managers, administrators, and teachers about how tasks are being designed and roles understood. Researchers have linked cyberloafing with such dysfunctions as job burnout (Aghaz & Sheikh, 2016; Oravec, 2002) and procrastination (Lavoie & Pychyl, 2001). Employees or students who have a great deal of time on their hands could turn to cyberloafing simply as a way to mitigate boredom. In some contexts, allowing individuals the leeway to engage in cyberloafing when there is little to do on the job than wait for the next customer can improve employee morale and actually improve overall productivity; this form of personal autonomy may help the employee retain alertness and optimism.

Cyberloafing research and policy development have often served to expand research and practitioner perspectives on the work/play dichotomy. Play (including unfettered exploration in a task-related environment as well as experimentation in personal expression) has been shown to help individuals prepare for the unexpected by presenting varying streams of novel or challenging situations (Oravec, 2015). Play is often construed as an underpinning for children’s intellectual and social development (Oravec, 2000), but how it functions for adults is

less clear. Creating venues for stimulating and invigorating online play in organizations can be a part of constructive recreation. These constructive recreation approaches are not designed to be coercive or compulsive recreation (forced on employees), but opportunities for exploration and expression that are in keeping with the social and cultural settings of the workplace.

Technological approaches to constraining cyberloafing have included surveillance of employee and student activity (Glassman, Prosch, & Shao, 2015). However, monitoring of individuals’ activities in many kinds of jobs (especially knowledge work, creative activity, and technological design) may not provide an accurate measure of their productivity (Oravec, 2004b). Social and policy approaches to cyberloafing have ranged from draconian rules that employees be fired for non-sanctioned computer use to perspectives that are more lenient and situation-sensitive (Block, 2001). Participatory and peer-oriented strategies that permit teams to establish their own affordances and limitations concerning online recreation can help to integrate the knowledge that team members have about their local circumstances as well as harness peer pressure to help deal with specific problems. Simply creating a climate of fear, one in which some small slippage or discretionary break could result in a large penalty) can serve to undermine the benefits of advanced technology innovations and constrain employee openness and creative thinking (Zoghbi-Manrique-de-Lara, 2006).

FUTURE RESEARCH DIRECTIONS

Future directions for research on cyberloafing include its expanding group or collaborative orientations, moving away from the model of cyberloafing primarily being conducted by a solitary and isolated individual. Group-oriented or collaborative cyberloafing provides an attractive venue for individuals to become acquainted or deepen relationships in organizational contexts. However, when individual employees or students

use computers to structure large recreational projects (especially involving sports) dangers can emerge. For example, use of computer networking for office betting pools during “fantasy” sports or major athletic competitions may indeed enhance group cohesion but can also present sizable distractions, often transforming the character of the workplace and diminishing productivity. Research is needed as to how far these large-scale recreational efforts can be supported by organizations before social and task-related damage can occur, including injury to those who are excluded by the group or choose to exclude themselves (for whatever reason).

Cyberloafing is becoming an increasing concern in educational and workplace contexts as the opportunities to spend time on devices and with applications not related to school and work efforts increase. “Eduloafing” can also emerge as a problem as employees use computers to access educational applications in a way that is not in synch with their other organizational activities, potentially resulting in safety and distraction issues. Future directions in research involve understanding why individuals engage in cyberloafing and whether organizations can develop strategies for ensuring that whatever cyberloafing occurs is life-enhancing as well as conducive to productivity. For example, Wagner et al. (2012) explore how the lost sleep time of employees related to daylight savings time shifts can affect the amount of cyberloafing conducted in workplaces. Employee and student self-awareness of individual capabilities and limitations in terms of task alternation and multitasking could help in understanding these phenomena (Adler & Benbunan-Fich, 2013). Compulsive use of online recreation during work or school could signal larger, serious issues involving Internet addiction. Like many other forms of mental health issues, Internet addiction could be debilitating for individuals who cannot balance their online activities with other aspects of their lives; it may need to be handled with advanced medical consideration (Burnay, Billieux, Blairy, & Larøi, 2015).

Yet another emerging research direction involves the “gamification” of workplace and educational efforts (Deterding, Dixon, Khaled, & Nacke, 2011). A growing number of gamification and multigamification initiatives (ways of using gaming approaches and methodologies in everyday activity) have been directed toward infusing game-like components to organizational activity, in part as stress relief but also to increase the engagement of organizational participants (Oravec, 2015). In the near future with gamification initiatives, computer technology applications in workplace and classroom settings may be so attractive and engaging that the basic concept of “cyberloafing” could be problematic; work itself may become increasingly appealing if not addictive (as it apparently already is in some workplaces).

CONCLUSION

Cyberloafing has been shown by some researchers to be a stress reducer, often playing roles in enhancing job performance and even in stimulating creativity. In workplaces in which long hours and intense focus are the norm, such diversion is often perceived as essential in maintaining mental health (Tapia, 2004). However, other researchers and practitioners have stressed the potential hazards cyberloafing presents in terms of decreases in productivity as well as increases in safety concerns as individuals are distracted or disoriented (Lim & Chen, 2012). Situational approaches that incorporate “constructive recreation” strategies can help organizational participants deliberate safety and social problems and map out potential solutions (Oravec, 2002; 2004a). For example, in many knowledge work settings in which computing technology plays substantial roles cyberloafing may be an acceptable way of taking a break in order to regain perspective or generate new ideas; in other settings (such as controlling heavy machinery) a similar approach toward taking breaks could result in tragedy. Such technologies as smartphones and smartwatches make it increasingly feasible

for employees and students to be surreptitious in their cyberloafing. Important and complex new issues are also emerging as individuals “eduloaf” by engaging in immersive educational experiences while on the job, possibly setting themselves up for cognitive overload.

As outlined in this article, cyberloafing phenomena have changed in character over the past several decades with advances in technology making computing more collaborative (with social media) and more personal (with mobile and wearable technologies). Cyberloafing will probably take on even more new forms as computer technology is integrated ever more closely into our everyday lives. The individual who focuses on his or her smartwatch to ascertain stress levels or monitor heartbeats may be conceived as a form of “cyberloafing” (for taking time out of assigned work hours for these tasks). However, without monitoring the wearable technology, the employee may eventually suffer in terms of health. If this individual works in an air controller facility and has jets to monitor, the situation may be viewed as quite different from that of the office worker who is handling routine paperwork and takes a quick break between cases. Equipping employees and students to be aware of their personal capabilities in terms of alternating between work and play, as well as to be conscientious and sensitive to others’ needs in their use of computer technology in recreation, will be part of the overall movement in organizations to mitigate the dysfunctional aspects of cyberloafing.

KEY TERMS AND DEFINITIONS

Constructive Recreation: Recreation is “constructive” when it is in synch with pending work responsibilities, allowing individuals to use time not consumed by workplace demands in ways that equip them to face future tasks with greater energy and expanded perspectives (Oravec, 2002). Constructive recreation is also in keeping with technological constraints, as exemplified by the organizations that allow online recreation but place limits during certain hours to avoid system overload.

Cyberbludging (or “Cyber Bludging”): Workplace and community cyberloafing in Australia and some other nations is often labeled as “cyberbludging” (Hernandez-Castro, 2016; Liaskos & Sandy, 2004), with the word “bludging” having the connotation of a “shirking of responsibility.”

Cyberslacking: A use of computer equipment or computer networking interaction in a way that is not in keeping with the overall goals of the organization. The term is often associated with the activities of individuals who are younger in relation to the average age of employees and managers in the workplace.

Gamification: Generally characterizes approaches through which video games and other technology-enhanced gaming systems (such as video games and virtual reality) are being used to transform workplace activities. Strategies for gamification can vary from simple contests to

complex segments derived from familiar or newly-invented games.

Internet Addiction: Syndrome in which individuals engage in compulsive behavior in relation to their Internet activity. Researchers and practitioners have sometimes construed Internet addiction as merely one form of compulsivity and others differentiate it because of its computer-related focus and the particular qualities of Internet interaction.

Mindfulness: The state of engaging in conscientious and focused attention to the current task at hand and one’s own associated mental state, or upon a limited and constrained set of stimuli.

Multitasking: Attempts to parcel or divide attention between or among two or more tasks. In the context of cyberloafing, this would entail attempting to engage in recreational activity at the same time one is immersed in a workplace project.

Serious Games: Games that are directly developed for the purpose of enhancing some aspect of educational, political, social, or workplace interaction. Serious games can serve to deepen the players’ understandings of some dimensions of the human experience, often providing the capability to experiment with and explore in depth different aspects of social and interpersonal interaction.

Stress Reduction: Approaches to assist individuals in coping with stressors in various contexts, such as workplaces and schools. Stressors include noxious or toxic aspects of the social or physical environment as well as overbearing demands for personal performance.

Time Theft: A use of time on the job that involves matters not productively related to employer and organizational concerns. Individuals who engage in time theft can be seen as committing offenses against their employers as well as against their co-workers who must make up for their lost efforts.

Influencing People and Technology Using Human Resource Development (HRD) Philosophy

INTRODUCTION

Historically, and notably since Zakaria's (2010) statement that "technology and globalization are shattering the middle class" in America (p. 31), American workers are continuing to be displaced by the productivity gains of technology and the competition for cheap laborers in a globalized economy. Human Resource Development (HRD) professionals are seeking ways to address rapid, continuous changes in technology and some, unfounded, fears and concerns regarding the influence of globalization on middle class workers. Globalization efforts do not need to equal unemployment for American middle class workers. Globalization can add opportunities for American middle class workers to increase their job prospects by learning new skills including how to leverage technological innovations for their advantage within the global job market. HRD professionals have an opportunity to assist workers with their skill development and improvement.

HRD professionals are engaged with workers in training and development, career development, and organization development initiatives (Mankin, 2001; Swanson & Holton, 2001). These initiatives are vital to employee development within organizations and many employees seek training and development opportunities so that they can

build successful careers and the ability to adapt to organizational and marketplace changes.

Workers are beginning to recover from the Great Recession of 2007 and HRD professionals are tasked with making their employees' recovery more viable. Aguinis and Kraiger (2009) suggest that there was "[a]n important challenge for the practice of training... to integrate the training function with employee selection, performance, management, rewards, and other human resource practices (Aguinis, 2009; Aguinis & Pierce, 2008; Cascio & Aguinis, 2005)" (p. 467). Their assessment is currently still needed and will be needed for the foreseeable future as artificial intelligence using robots, computer technology, simulations, avatars, and other technological innovations are being used to realign and displace workers. The current post-fordism era is associated with significant changes to American culture, organizations, and individuals (Heffernan, 2000). However, the influence of technology on the development of people has rarely been discussed within the HRD research literature (Githens, Dirani, Gitonga, & Teng, 2008; Hughes, 2010; 2012).

HRD, a relatively new field of study, has scholars and professionals who are continuously examining and testing its theories and philosophy. Organizations are mutable and strive to succeed through the people and technology in which it

invests and employ. The management and development of both people and technology is essential to the competitive advantage of organizations. The management of these critical domains is led by individuals whom often have limited interaction and different vantage points through which they examine and determine success. The dynamics of HRD theory and philosophy on the relationships between people and technology within organizations is an area requiring more exploration within the HRD field.

This chapter explores the extent to which HRD philosophy influence the relationship between people and technology. We have examined whether or not HRD professionals and researchers deny that there is a viable relationship between people and technology, and whether or not HRD professionals and researchers are limiting the field because of their ethical beliefs which juxtapose people to technology.

BACKGROUND

HRD has evolved from sociology, to business, to education and is still looking for a place of its own within academia (McLean, Lynham, Azevedo, Lawrence, & Nafukho, 2008). HRD has a rich history that is not well known or explained in the HRD research literature (Gosney, 2014; Gosney & Hughes 2015). Without an explanation and chronicling of its history, HRD's search for a clear philosophy is continuous and debatable amongst HRD researchers and professionals.

HRD Theory Building

Swanson (2001) identifies three foundational theories of HRD: psychological theory, economic theory, and systems theory that make up the legs of his three-legged stool model; however, they are not the only theories that can support the field. Some of the theories that have contributed to defining HRD are as follows:

1. Commonly held theories of HRD (Weinberger, 1998);
2. Operational definitions of expertise and competence (Herling, 2000);
3. Organization development: An analysis of the definitions and dependent variables (Egan, 2002);
4. An investigation into core beliefs underlying the profession of HRD (Ruona, 1999); and
5. Philosophical foundations of HRD practice (Ruona & Roth, 2000).

There are also examples of HRD theory building efforts which include:

1. Systems theory applied to human resource development (Jacobs, 1989);
2. Foundations of performance improvement and implications for practice (Swanson, 1999);
3. A theory of intellectual capital (Harris, 2000);
4. A theory of knowledge management (Torraco, 2000); and
5. The development and validation of a model of responsible leadership and performance (Lynham, 2000).

These theory building efforts have all contributed to the emerging field of HRD; however, McLean et al. (2008) suggested that HRD has much to learn from "EVERY field and discipline that touches on human behavior" (p. 249). Gosney (2014) and Gosney and Hughes (2015) propose in Gosney's Model of Modern Era Theory & Practice Generation in HRD that HRD theory and practice is influenced from a variety of sources, including philosophy and psychology. Openness to new concepts and formulations provide opportunity for continuous development within HRD.

HRD Philosophy

An oftentimes unexplored element of theory-building is an examination of the philosophies upon which the theory rests. Philosophy, literally

defined as the love of wisdom (Jaspers, 1951), is the continuous search for understanding of how the universe works. Or, as aptly described by Paulsen (1907), “[i]n the most general sense of the term, philosophy is simply the continually-repeated attempt to arrive at a comprehensive and systematic knowledge of the form and connection, the meaning and import of all things” (p. 2-3). Inherent in that comprehensive and systematic knowledge are assumptions – assumptions of time, space, and purpose. As Whitehead (1926) noted, “Every philosophy is tinged with the colouring of some secret imaginative background, which never emerges explicitly into its trains of reasoning” (p. 9). Jaspers (1951) suggests that “there is no escape from philosophy. The question is only whether a philosophy is conscious or not, whether it is good or bad, muddled or clear. Anyone who rejects philosophy is himself unconsciously practicing a philosophy” (p. 12).

If we are to take Jaspers (1951) at his word, HRD practices a philosophy through the theories it espouses and methodologies it embraces. Those theories, then, carry with them assumptions – assumptions regarding free will, purpose, even of the nature of time (Gosney & Hughes, 2015). Gosney and Hughes (2015) explore the history of HRD with the specific intent of unearthing the underlying philosophies of HRD and the assumptions upon which those theories rest. They identify three major philosophical influences on HRD theory and practice: Empiricism, Humanism, and Systems Theory. Each philosophical pillar undergirds much of how HRD is realized both in theory and in practice today.

Empiricism as an informing philosophy became distinct in HRD at the rise of the Industrial Revolution (Gosney & Hughes, 2015) and evidences can be seen in both current theory and practice. As a discipline that borrows heavily from the social sciences (Reio & Batista, 2014), HRD has embraced an empirical methodology in testing theory (Callanan & Connor, 2015; Nimon & Astakhova, 2015). It has also leaned upon empirical and positivist philosophy in the development

of tools such as personality assessments (Lohman, 2004; Messmann & Mulder, 2012), selection and job-fit assessment (Berr, Church, & Waclawski, 2000), and instructional design and learning (Mazur, 1994; Wilson, Jonnassen, & Cole, 1993).

Humanism is a philosophy that has noted influence in HRD theory, as evidenced by Vince (2003) who suggests that “HRD policies and practices have traditionally been informed by a tired humanism . . .” (p. 559). This humanism, with its genesis in the Human Relations movement post-Industrial Revolution (Barnard, 1938; Follett, 1919; Mayo, 1945) directly impacts HRDs conceptualization of employee engagement and its attendant influence on organizational productivity (Cardus, 2013; Elliott & Turnbull, 2003; Shuck & Rocco, 2014). In its influence of HRDs conceptualization of employee engagement, humanism influences HRD theory. Humanism also influences HRD practice through its methods of executive coaching (Athanasopoulou & Dopson, 2015; Mulvie, 2015) as well as learning and instructional design methodologies (Hiemstra & Brockett, 1994; Knowles, Holton, & Swanson, 2015).

Finally, the philosophy of systems theory is pervasive in both HRD theory and practice. With roots in Aristotelian teleology (Bertalanffy, 1969; Falcon, 2015), systems theory rose to prominence as an influencing philosophy of HRD in conjunction with the emergence of Organization Development (Gosney & Hughes, 2015; Swanson, 2001b). Systems theory as a philosophy informs HRD theory most definitively in the arena of change management (Hayes, 2014) but also in theory-building around how knowledge is disseminated throughout an organization (Hughes & Gosney, 2016a; Senge, 1990). The influence of systems theory philosophy in the practical aspects of HRD are also apparent, such as the utilization of survey search (Likert, 1958) communities of practice (Chang & Jacobs, 2012) and action learning methodologies (Yeo & Marquardt, 2015). Kuchinke’s (2000) call for institutional theory (a systems theory coming out of sociology) to be utilized as a frame-work for HRD research

is another example of the influence of systems theory philosophy in HRD.

While Gosney and Hughes (2015) have explored the underlying philosophies of HRD, there is as of yet a lack of general awareness on the part of both theoreticians and practitioners of the influence of philosophy on the discipline. While HRD is not alone in such lack of awareness (Slife, 2000), and while others within the discipline have called for a more robust and thorough approach to philosophy within HRD (Ruona & Lynham, 2004), HRD has yet to fully embrace and explore the influence of philosophy on its attendant theory and practice. The reasons for this are likely numerous, but among them may be the influence of an additional philosophy that is predominant in the environment in which HRD is currently practiced: pragmatism. Gosney (2016) explores the influence of pragmatism on HRD today, particularly as a potential cause for the challenges in bridging the gap between scholars and practitioners in HRD.

As HRD matures as a discipline, and as new theories and methodologies emerge to meet the challenges of today's organizations, the influence of philosophies and their underlying assumptions will continue unabated. There is historical and current evidence to suggest that a number of philosophical influences, such as empiricism, humanism, systems theory, and pragmatism (Gosney, 2016; Gosney & Hughes, 2015), wield notable influence on both the theory and practice of HRD. As new theories and methodologies are proposed it benefits the discipline to acknowledge and consider these philosophical assumptions – particularly as they relate to assumptions of the individuals to whom the theories and methodologies will be applied.

People, Technology, and HRD

Much of the research regarding technology and HRD centers upon computer technology and how it relates to educating employees in the workplace. Performance management systems, performance support systems, Learning Management Systems

(LMS's), enterprise social networks (e.g., Yammer), social networks (e.g., Twitter, Facebook), professional networks (e.g. LinkedIn) and mobile devices that manage employee training and development, career development, and organization development are important tools for HRD professionals. Current trends suggest the need for organization's to be device agnostic, so employees can bring their devices to work and use the device of their choice in the workplace. HRD professionals and researchers must go beyond managing the systems to helping employees operate technological equipment. These types of technology systems that are displacing middle class workers (Zakaria, 2010) because they are not equipped or educated to operate high technology and cannot be trained quickly enough to meet the global needs of organizations. Instead, companies are bringing in foreign workers to meet immediate workplace needs in the US.

Due to the workplace realities of this millennium, HRD must recognize the need to support employees who are likely to have several short tenure positions within multiple organizations across their careers. HRD can embrace this trend and ensure that their employee develop transportable and marketable information technology (IT) skills. Examples of such skills include the ability to create a web page, troubleshoot software, and debug hardware. To aid the development of technological competencies, HRD will need to facilitate employees' adoption of a technology identity if HRD is to drive meaningful employee and organizational change. Possessing a technology identity will fuel individuals' desire to be lifelong technology learners and developers of technology. This will benefit the employees, their organizations and the broader society.

Githens, Dirani, Gitonga, and Teng (2008) conducted a meta-analysis of technology-related research in HRD publications from 2000 to 2006. Their findings revealed that only 10% of 1675 articles in five journals were related to technology; implying a lack of interest in technology by HRD researchers and professionals. This is discouraging

because Swanson (2008) noted the following assumptions regarding the role of human expertise and skill they bring to organizations:

1. Organizations are human-made entities that rely on human expertise in order to establish and achieve their goals.
2. Human expertise is developed and maintained through HRD processes for the mutual long-term and short-term benefits of sponsoring organizations and individuals involved.
3. HRD professionals are advocates of individual, team, work-processes, and organizational integrity. (p.331)

If HRD is to advocate the success of work processes, how can they do so without an understanding of technology's role in workplace success? How can HRD retool its workforce without first looking at their own technology skillset? It is difficult to model or advocate behavior that you do not personally use. People and technology are essential to the functioning of an organization. Hughes' (2010) People as Technology Conceptual Model is an integrative part of an organization's value creation strategy.

The PT conceptual model described the potential value that technology development and people development can bring to an organization. Operationalization of this model (Hughes, 2012) has the potential to be a promising management practice (Espedal, 2005) that will provide a solution when organizations struggle to implement their best practices without the best people in the right jobs at the right time and the best technology (Brache, 2002; Espedal, 2005; Martelli, 1998; Pfeffer, 1994; Stewart, 1997). People and technology must blend to the extent that the process is a win-win for employees and organization (London & Diamante, 2002). This concept is useful within all business strategies including JIT, Lean manufacturing, ISO, TQM, and Six Sigma because it enhances the foundation of the strategy, the people, and the process (Snell & Dean, 1992).

Much of the HRD technology related research "focused on educational technology in higher education settings, while non-profit organizations and government/military settings were under-represented. Overall, non-training topics were [also] underrepresented" (Githens, et al., 2008, p. 1). The opportunity for research in technology related research within HRD is extensive and needed. Re-training of the American workforce in high tech skills is an area where HRD researchers and professionals' skills are warranted. Training and development and career development areas of HRD in particular are being influenced by the technological advances that are being made in the global economy (Zakaria, 2010). How organizations adjust to these developments impacts the future of its employees and its existence.

FUTURE TRENDS

HRD is continuously evolving as organizations are continuously changing processes and procedures, developing employees, and trying to remain competitive in a global economy.

HRD professionals and researchers must also be willing to continuously change and evolve to help organizations achieve their goals. Some of the key strategies are:

1. HRD professionals and researchers must end the debate about which is more important between people and technology (Hughes, 2010, 2012; Kuchinke, 2000; Murphy & Garavan, 2009) and begin to learn from every field that touches human behavior (McLean et al., 2008). A focus on the history or organization theory and its evolution from sociology to business to HRD would enhance the development and understanding of HRD philosophy (Gosney & Hughes, 2015).
2. HRD professionals and researchers must find a way to bridge the gap between research and practice (Hughes & Gosney, 2016b). They must come to terms with the fact that

organizations are struggling to reach their goals without effective and efficient strategies from the HRD field.

3. HRD professionals and researchers must understand the relationship between people and technology (Hughes, 2014) and not focus on one or the other in isolation. They must develop methods of valuing both people and technology within the workplace (Hughes, 2012).
4. Technological innovations in the workplace continues an explosive upward trend. HRD researchers and professionals must understand these innovations to ensure that as people are developed their roles are not diminished or further eliminated but enhanced by technology.
5. HRD professionals and researchers must work to meet the business needs of workers in all organizations and provide technological based solutions along with their people based solutions. HRD professionals and researchers cannot plan people strategies without understanding technological implications (Betz, 1993; Hughes 2014).
6. Ultimately, HRD must consider public policy as a potential future area of research. Understanding the broader labor relations and economic implications of their decisions within the public policy arena can only strengthen HRD practice.

CONCLUSION

HRD professionals and researchers do not appear to deny that there is a relationship between people and technology; yet, there is very limited research that supports their effort to understand the relationship of people and technology within organizations. HRD professionals' and researchers' ability to expand their research and practice are limited by their beliefs concerning the juxtaposition of people to technology and/or their focus upon issues that are not adding to the

knowledge base in these specific topic areas. A mind shift needs to occur before progress can be made in this area of inquiry: people, technology and HRD. Understanding the history, philosophy and theories of HRD provides an opportunity for HRD researchers and professionals to build a solid foundation upon which they can enhance human behavior within organizations. They can begin to blend research and practice in a way that allows individuals and organizations to thrive and achieve competitive goals. It will also allow them to value the relationship between people and technology so that organizations can maximize the efforts of both people and technology and not one or the other (Carrig & Wright, 2006). Without these changes HRD professionals will never win a seat at the 'table' in corporate America or any other organization even though it is central to training and development, career development, and organization development. The future is optimistic for HRD researchers and professionals, and there are numerous ways that HRD can be developed to transform institutions to meet organizations' needs for global competitiveness.

KEY TERMS AND DEFINITIONS

Axiology: The study of the nature, types, and governing criteria of values and value judgments.

Epistemology: The branch of philosophy that studies the nature of knowledge, in particular its foundations, scope, and validity.

Exogenous: Originating outside an organism or system.

Globalization: To become international or start operating at the international level, or cause something, especially a business or company, to become international.

Mutable: Tending or likely to change.

Ontology: The most general branch of metaphysics, concerned with the nature of being; the study of existence.

Operationalize: To put something to use or into operation.

Philosophy: A set of basic principles or concepts underlying a particular sphere of knowledge.

Performance Appraisal

Chandra Sekhar Patro

Gayatri Vidya Parishad College of Engineering (Autonomous), India

INTRODUCTION

In every organization, employees play a crucial part in determining its growth and survival. Employees are the eventual assets of any organization. The relation between the appraisal structure and the organization's approach is used as a strategic tool to accomplish the organization's vision. Performance appraisal is a controversial management tool searching for answers to ubiquitous tribulations in system design and administration (Thayer, 1987). This will evidently be a key factor in communicating values, promoting flexibility and maximizing individual potentials and contributions. Performance appraisal is a formal management system which evaluates the quality of an individual's performance in an organization. Performance appraisal is defined as a systematic description of individual job-relevant strengths and weaknesses, for the purposes of decision making regarding an individual's performance. In another term, performance appraisal is a process of evaluating the behaviour of the employees in the workplace, or it can also be referred as a process of giving feedback on employees' performance. The practice of performance appraisal tool has become the heart of the human resource management system in the organizations. It is a tool not only for accessing the performance of the employees but also the whole organizational performance.

The concept of performance appraisal was first time used during the First World War. At the instance of Water Drill Scott the U.S Army adopted the Man to Man rating system for evaluating military personnel. This concept came for industrial workers during 1920-30 under which efficient workers used to be identified and paid wages incentives and that scheme was popu-

larly known as "merit rating programs". In the early fifties, performance appraisal techniques began to be used for technical, professional and managerial personnel. Performance appraisal is a developmental tool which is used for all round development of an individual. It is the assessment of performance on an individual in a systematic way (Armstrong, 2006). It helps identify ways to improve one's job performance thus benefiting organization and the society as a whole. Rao (2005) defines that "performance appraisal is a method of evaluating the behaviour of employees in the work spot, normally including both the quantitative and qualitative aspects of job performance."

The term performance appraisal is sometimes referred as performance review, employee appraisal, performance evaluation, employee evaluation, employee rating, merit evaluation, or personnel rating. Performance appraisal is a system that involves a process of measuring, evaluating, and influencing employees' attributes, behaviour and performance in relation to a pre-set standard or objective. Usually, the appraisal of employee's performance is prepared by his immediate supervisor or manager. This process normally requires the supervisor to fill out a standardized assessment form that evaluates the individual on different dimensions and then discuss the results of the evaluation with the employee. In most of the organizations the performance appraisal systems stay one of the immense paradoxes of effectual human resource management. The appraisal system provide valuable performance information to a number of critical human resource activities, such as the allocation of rewards, e.g., merit pay, promotions; feedback on the development and assessment of training needs; other human resource systems evaluation, e.g., selection predictors; and

DOI: 10.4018/978-1-5225-2255-3.ch376

performance documentation for legal purposes (Cleveland, Murphy, & Williams, 1989). Efficient implementation of the performance appraisal process can help the organization in diverse ways. This process offers the benefit of identifying the employees' skills and serving the employees' development needs and career ambitions.

BACKGROUND

Performance appraisal is a complex tool of the human resource management process in any organization. Performance appraisal is not just about rating employees, it is a basis for administrative decisions such as promotion, allocation of financial rewards, employee development and identification of training needs (Meenakshi, 2012). Appraisal is preceded by establishing common objectives or a description for the job, identifying precise job expectations, providing feedback and, when necessary provides coaching (Hillman, Schwandt, & Bartz, 1990). The assessment of employees' performance is one of the most common practices in almost every organization, and so performance appraisal is an essential procedure for the better performance of employees and the organization itself (Karimi, Malik, & Hussain, 2011). Fletcher (2004) believes that the general aims of performance appraisal also include motivating staff, succession planning and identifying potential, promoting manager-subordinate dialogue and formal assessment of unsatisfactory performance. Many businesses regularly use performance appraisal scores to determine the distribution of pay, promotions, and other rewards; however, few organizations attempt to evaluate how employee perceptions of performance appraisal fairness impact employee attitudes and performance (Swiercz, Bryan, Eagle, Bizzotto, & Renn, 2012). The organizations should implement performance appraisal practice in the best possible way; there is the need to develop a good feedback system, appropriate and adequately filing, discussing appraisal results, design ways to

communicate appraisal results, review appraisal on due attention, participatory appraisal rating system and have to design procedure to make aware of every employee about the appeal process (Bekele, Shigutu, & Tensay, 2014).

According to Cawley, Keeping, & Levy (1998) subordinates reactions to performance appraisal can be a way of measuring their outlook towards the system. The main reactions that can be assessed are their satisfaction from the appraisal, the utility, whether they felt they were fairly appraised, how motivated they were from the appraisal and the accuracy of the system. Poon (2004) identified the usefulness of performance appraisal as a managerial decision tool depends partly on whether or not the performance appraisal system is able to provide accurate data on employee performance. Rees and Porter (2003) stated 360-degree appraisal as a process that involves the key people in a person's network of working relationships making assessments of an employee's performance and their subordinate being appraised is then given structured feedback; this may involve feedback from subordinates and any key outside parties, if it is practicable. DeCenzo and Robbins (2007) feel that appraisers should only rate in those areas in where they have substantial job knowledge. They should be as close as possible to the organizational level of the employee being evaluated. If the appraiser is not in a position where they can observe the persons work behaviour then there is a greater chance of inaccuracies.

According to Muo (2007) performance appraisal entails the systematic, organised and formalised process of evaluating individual employee's job related strengths and weaknesses with a view to providing feedback on which performance adjustment can be made. Thus, performance appraisal has both evaluative and developmental objectives. Nickols (2007) argues that the performance appraisal takes lot of time and energy, and can create frustration that can undermine the teamwork and climate of trust. Lack of communication, very variable appraisal standards and personal biases and values that replace organization standards,

etc., are all factors that influence the appraisal process. Gibson, Harvey, & Harris (2007) viewed that performance appraisal form a foundation for many human resources functions, effectively setting the standards to drive recruiting efforts, and it is customary to use these criteria in hiring, promoting, evaluating and equitably compensating employees, and forming the basis for many employee training programmes. Boachie-Mensah & Seidu (2012) advises that employees are likely to embrace and contribute meaningfully to the performance appraisal scheme, if they recognize it as an opportunity for personal development, a chance to be visible and demonstrate skills and abilities and an opportunity to network with others, but if the employees perceive this as an unreasonable effort by management to try to closer supervise and gain control over tasks they carry out, they won't welcome the scheme as easily. Mwema & Gachunga (2014) argued that organizations should appraise their employees often through utilized targets, accomplishments, organization goals, time management and efficiency for performance measure purposes as it would lead to increased in employee's productivity.

OBJECTIVES OF THE STUDY

1. To examine the usefulness of various performance appraisal tools adopted in an organization.
2. To find out the employees' satisfaction level on performance appraisal process.
3. To explore the gaps and the recent trends in implementation of performance appraisal system in an organization.

CLASSIFICATION OF PERFORMANCE APPRAISAL TOOLS

Performance appraisals generally review the past behaviour and so provide an opportunity to reflect on past performance. But to be successful

they should also be used as a basis for making development and improvement plans and reaching agreement about what should be done in the future. Employee performance appraisal has two forms i.e., formal (systematic) and informal (non-systematic) appraisal. Informal appraisal means continuous evaluation of an employee by her/his superior during the work process (Dědina & Cejthamr, 2005). Formal employee appraisal is a formal organizational process conducted on a systematic basis in order to enable a comparison between the expected individual (group) and real performance (Giangreco *et al.*, 2012). Appraisal takes place annually between the manager and the employee. However there are number of trends that are changing the style and relationship of the appraisal.

According to the authors (Deb, 2006; Khurana *et al.*, 2010; Randhawa, 2007), traditional appraisal methods focus on performance i.e., paired or group comparisons, ranking, rating scales and reports, essay method, checklists, a critical/key incident method, forced choice and distribution methods, field reviews. On the other hand, modern methods are partly similar to methods focusing on the future that estimate an employee's growth potential. These methods are Management by Objectives, Assessment Centre, Behaviorally Anchored Rating Scales (BARS), Psychological Appraisals, 360 Degree feedback, and human resources accounting.

Some authors have proposed methods of performance appraisal that include the combination of both traditional and modern methods of appraising the performance of an employee. Mathis and Jackson (2011) classified checklists, graphic rating scales and Behaviorally Anchored Rating Scales (BARS) as scaling methods of performance appraisal and stated that the Narrative methods are used in cases requiring written or oral appraisal which includes free essay, reports and critical incident methods. In BARS, the ratter will act as observer not the judge. It helps the ratter to focus on specific desirable and undesirable incidents of work behaviour which can serve as examples

in discussing a rating. BARS use behavioural statements or concrete examples to illustrate multiple levels of performance for each element of performance.

Griffin (2012) stated that the appraisal methods such as Behaviorally Anchored Rating Scales (BARS), Rating Scales, Ranking and Comparison methods are targeted to evaluate and assess the current outputs of the employees under standardized conditions, and these are classified as Judgmental methods (Pride, Hughes, & Kapoor, 2012). Bogardus (2007) classified that appraisal techniques as comparative, rating, narrative, and behavioral methods. Comparative methods compare work performance of individuals - the most common type is the paired comparison, ranking, forced distribution method and forced choice method. The most common appraisal methods are checklists and rating scales. Finally, the group of behavioral methods covers the Behaviorally Anchored Rating Scales (BARS) method.

METHODOLOGY

The present study is an insight on the impact of practicing the performance appraisal system and the satisfaction experienced by the employees working in these organizations. For the survey, the employees (teaching and non-teaching staff) working in different private engineering colleges and located in Visakhapatnam city of Andhra Pradesh, India are considered. The staff members having a minimum five years of experience were considered for the study. The employees list was obtained from the official websites of engineering colleges and a simple random sampling method was employed for the study.

The data presented in the study are collected from both the primary and secondary sources. For the literature survey, secondary source of data is used from various published sources such as, books, journals, websites, and studies done previously by the researchers. The primary data

was collected from the respondents by distributing questionnaires personally through emails. The purpose of the study was explained to the employees and was asked to rate the scales. They were also assured of confidentiality of their responses. The questionnaire was sent or personally distributed to 200 employees and 120 valid and fair responses were measured for the study.

This study therefore seeks to investigate the employees' satisfaction towards the existing performance appraisal tools and fill this knowledge gap by determining the impact of performance appraisal on employee productivity in the organizations.

DATA ANALYSIS AND DISCUSSIONS

In the study, a descriptive analysis is performed to know the perceptions of the respondents with regard to the performance appraisal process. The responses for each specific statement are compared using the mean and standard deviation score. The degree of agreement or disagreement of the respondent for each statement is analyzed by using a five point scale ranging from Strongly Agree (5) to Strongly Disagree (1). To measure the level of employee satisfaction on the implementation of performance appraisal in their organizations, the mean and standard deviation of the indicators were analyzed with the help of descriptive statistics of SPSS software. The higher the mean score, the more that respondent agreed with the indicators and vice-versa. The standard deviation scores also indicate the degree to which responses varied from each other; the higher the SD score, the more variation in the responses. The results and findings with regard to the practice of performance appraisal process in the organizations are discussed in the paper.

The views of the respondents on the eleven indicators of performance appraisal process with mean and standard deviation scores are shown in Table.1.

Table 1. Employees' satisfaction level on performance appraisal process

Sl. No.	Indicators	Mean	Standard Deviation
1	Satisfied with existing appraisal process used to evaluate the performance	3.32	1.15
2	Performance appraisal process help me to know about my current performance level	3.51	1.20
3	The organization conducts performance appraisal in the best possible way	3.25	1.12
4	Encourage continuous feedback between the appraisee and the supervisor	3.05	1.19
5	Improve quality of work through better planning and fair participation in appraisal	3.28	1.15
6	Links the individual performance with organizational performance and goals	3.30	1.18
7	Current Performance appraisal process is fair and unbiased	3.28	1.15
8	If not satisfied with performance appraisal score, there is appeal process	3.10	1.10
9	The organization recognizes the good performers rather than criticizing the poor performers	2.95	1.22
10	Provide information on HR issues such as promotions, delegation, training, deployment, and rewards	3.20	1.19
11	Performance appraisal is valuable to me as well as to my organization	4.10	0.96
Total		3.29	1.14

The analysis on the level of respondents satisfaction on performance appraisal process shows that one indicator is high i.e., Performance Appraisal is valuable to me as well as to my organization with a mean score of 4.10 and SD of 0.96. The satisfaction level of respondents is moderate with mean score of 3.51 and SD of 1.20 for the indicator, performance appraisal process helps me to know about my current performance level. However, the respondent's level of satisfaction is low for the other eight indicators as the mean score ranged from a maximum of 3.32 to a minimum of 2.95.

As a result from this finding it can be generalized that, the respondents are not satisfied concerning with the existing appraisal process used to evaluate the performance (3.32, 1.15); organization conducts performance appraisal in the best possible way (3.25, 1.12); encourage continuous feedback between the appraisee and the supervisor (3.05, 1.19); improve quality of work through better planning and fair participation in appraisal (3.28, 1.15); links the individual performance with organizational performance

and goals (3.30, 1.18); current Performance appraisal process is fair and unbiased (3.28, 1.15); if not satisfied with performance appraisal score there is appeal process (3.10, 1.10); the organization recognizes the good performers rather than criticizing the poor performers (2.95, 1.22); and provide information on HR issues such as promotions, delegation, training, deployment, and rewards (3.20; 1.19).

The overall response for the eleven indicators specifies the mean score as 3.29 and standard deviation (SD) score as 1.14. Therefore, the mean score indicates that there is low level of satisfaction towards the current performance appraisal process, which implies that the respondents are dissatisfied. Thus, from the statistical analysis shown in table.1 it is observed that the intention of the employees towards the performance appraisal process practiced in their organizations is moderate and dis-satisfied. Therefore, such remarked areas of dis-satisfaction are the indicators and the root causes for employees' negative satisfaction regarding to the performance appraisal process of their organization.

GAPS IN IMPLEMENTATION OF PERFORMANCE APPRAISAL

The appraisal process should directly reflect an employee's performance and not on any biases of a supervisor. Generally, this is unworkable to do perfectly as most raters either intentionally or unintentionally commit errors. Raters need to be aware of these biases, so that their effect on the appraisals can be limited or eliminated. The important issues and discrepancies concerning performance appraisal in the present circumstances are:

1. Most of the indicators used for measuring the performance of the employees are not quantifiable in nature, making it difficult to measure the performance.
2. Appropriate information is not provided to the employees on the performance appraisal process followed in the organization and the appraisals are not conducted on regular basis.
3. The performance appraisal processes are faced with a lot of obstacles, the most prominent being lack of quantifiable indicators of the performance.
4. In some of the organizations the objectives are unchallenging, unrealistic and not timely reviewed and updated.
5. Due to the lack of accountability and job security, most of the employees have a *laissez faire* attitude towards their work.
6. There is often a lot of bias and subjectivity involved in the ratings given by the superiors due to unprofessional and unstructured approach towards the appraisal process.
7. Performance measuring, rating and review systems have become more detailed, structured and individual specific than before.
8. The focus of the performance appraisals is turning towards career development relying on the dialogues and discussions with the superiors.

RECENT TRENDS IN PERFORMANCE APPRAISAL

The problems in the implementation of the performance appraisal processes are being anticipated and efforts are being made to overcome them. Most of the organizations are moving towards 360-degree feedback system due to the various challenges faced by the management. The emergence of following concepts and the following trends related to performance appraisal can be seen in the global scenario.

1. **360 Degree Appraisal:** The 360 degree appraisal process is also known as 'multi-rater feedback' and is the most comprehensive appraisal where the feedback about the employees' performance comes from all the sources that come in contact with the employee on his job. Organizations are increasingly using feedback from various sources such as peer input, customer feedback, and input from superiors. Different forms with different formats are being used to obtain the information regarding the employee performance.
2. **Team Performance Appraisal:** Most of the performance appraisal techniques are formulated with individuals in mind i.e. to measure and rate the performance of the individual employee. Therefore, with the number of teams increasing in the organizations, it becomes difficult to measure and appraise the performance of the team. The answer to this problem that is being adopted by many companies is to measure both the individual and the team performance. Sometimes, team based objectives are also included in the individual performance plans.
3. **Rank and Yank Strategy:** This strategy of appraisal is can also be referred as 'Up or out policy'. It refers to the performance appraisal model in which best-to-worst ranking

methods are used to identify and separate the poor performers from the good performers. Then the action plans and the improvement opportunities of the poor performers are discussed and they are given to improve their performance in a given time period, after which the appropriate HR decisions are taken. Some of the organizations following this strategy are Ford, Microsoft and Sun Microsystems.

4. **Information and Communication Technology:** The adoption and utilization of Information and Communication Technology (ICT) in performance appraisal is gradually becoming a major requirement for improvement in the efficiency and effectiveness of employee performance and productivity. The emergence of technology has brought great changes in evaluating the performance of the employees. The innovations in information processing, telecommunications and related technologies, known collectively as information and communication technology (ICT) is having profound impact public as well as organizations by easing enquiry, saving time, and improving service delivery (Yasuharu, 2003). The rapid advances in technology drastically changed the traditional ways in which information was processed, communications conducted, and services made available (Sarfo, 2007). The technology based appraisal will help the organizations in perceived usefulness, saving time and other resources. This method is practiced in many large organizations where the usage of technology has become more essential.

Instead of measuring employees' performance and pointing out where they fall short, the organizations will achieve more results by finding ways to fine-tune and improve their systems. These days the managers just need to document that they have in fact had regular conversations with their employees and if there are any problems the

managers are expected to make note of it. This creates the paper trail that will support any eventual disciplinary action or termination.

FUTURE RESEARCH DIRECTIONS

In the present conditions, organizations need to adopt new performance appraisal tools that allow greater involvement of both the raters and the ratees. Just like other management practices the employee appraisal process should also be dynamic. There is continuous need for reviewing and updating the appraisal process to match along with the organizational changes and current management practices. Performance appraisal as a controversial tool of human resource tool also needs the whole system to be transparent and have control in each step.

This study highlights employees' satisfaction on performance appraisal and the gaps in implementation of appraisal system. But the research on how to establish control, appeal and transparent system is limited in this study. Therefore, for further studies, it is important to explore how the organizations can establish the formal appeal and control system, and keep transparency in performance appraisal. This study can be further enhanced to know the execution of technology based appraisal process and improve the system specifically, and make it work professionally.

CONCLUSION

A quality performance appraisal process must be put in practice by an organization to exert the employee's maximum efforts towards realization of organizational objectives and goals. In situations where employees are not aware of what they are expected to perform and the consequences that their performance would bring to them, it is difficult to anticipate better work performance and commitment towards the organization. The objective of this study was to assess the impact

of performance appraisal on employees' performance, as performance appraisal has been a controversial tool with its long lasting impacts on the employees' efficiency and overall organizational productivity. Thus, the findings of the study show serious managerial implications in order to create a good perception in the minds of the employees. In doing so, the organization may have to implement performance appraisal practice in the best possible way so as to change the perception of employees by realizing their needs. The outcomes of the study indicate that the negative perception of employees towards performance appraisal process has its own impact on the employees' work performance and overall organizational productivity.

The organizations should have to give due attention to continually improve and maintain employee affective organizational commitment and should make conscious efforts by creating different mechanisms like creating trust on the mind of employee about performance appraisal, establishing organizational plans for the career and development of employee, and providing opportunity to employee to suggest improvement in the ways things are done. Therefore, the management should introduce better incentive, opportunity for internal growth and development, smooth and transparent work communication system.

KEY TERMS AND DEFINITIONS

360 Degree Feedback: The information regarding the performance of an employee is derived from a number of stakeholders like immediate supervisors, team members, customers, peers and self.

Appraise: An individual being evaluated on work performance.

Appraiser: An individual responsible for evaluating an individual's work performance.

Behaviorally Anchored Rating Scales (BARS): Behaviorally Anchored Rating Scales is a formatted performance appraisal method based on making rates on behaviors or sets of indicators to determine the effectiveness or ineffectiveness of employees work performance.

Management by Objectives (MBO): In this method, the managers or employers set a list of objectives and make assessments on their performance on a regular basis, and finally make rewards based on the results achieved.

Performance Appraisal (PA): Performance Appraisal is a process of evaluating the employee's performance in terms of job requirements and setting job standards in an organization.

Psychological Appraisal: This method assesses the employee's potential for future performance rather than the past one. It focuses on the employee's emotional, intellectual, and motivational and other personal characteristics affecting his/her performance.

Work Performance: It is an accomplishment of the assigned tasks for achieving organization's goal.

Promoting Strategic Human Resource Management, Organizational Learning, and Knowledge Management in Modern Organizations

Kijpokin Kasemsap

Suan Sunandha Rajabhat University, Thailand

INTRODUCTION

The added value of human resource management (HRM) is strongest when HRM decisions are linked to organizational strategy (Schalk, Timmerman, & van den Heuvel, 2013). Strategic human resource management (SHRM) practices are developed, implemented, and executed based on a deliberate linkage to organizational strategy (Huselid, Jackson, & Schuler, 1997). SHRM predicts electronic human resource management (e-HRM) outcomes and the relationship appears context-dependent in modern organizations (Marler & Fisher, 2013).

Learning has an important position in the development of employees and their expertise (Melo & Beck, 2015). Organizational learning theory indicates that knowledge must be integrated throughout organization to facilitate strategic renewal (Lionzo & Rossignoli, 2013). Organizational learning incorporates the organizational system, dynamic mechanism, and effective HR activities toward improving the competency and capability of organizational employees in the modern workforce (Sabir & Kalyar, 2013). Organizational learning can significantly improve the family firms' ability to counter by stimulating entrepreneurship (Zahra, 2012). Knowledge management (KM), strategic orientation, and organizational innovation are correlated with organizational performance (Kasemsap, 2014a).

This article aims to bridge the gap in the literature on the thorough literature consolidation

of SHRM, organizational learning, and KM. The extensive literature of SHRM, organizational learning, and KM provides a contribution to practitioners and researchers by describing the theory and applications of SHRM, organizational learning, and KM in order to maximize the value of SHRM, organizational learning, and KM in modern organizations.

BACKGROUND

Strategic human resource management (SHRM) literature emerged about 30 years ago (Lengnick-Hall, Lengnick-Hall, Andrade, & Drake, 2009). The strategic evolution perspective explains how the expected outcomes of SHRM may vary depending on what decisions are made and what paths are taken in implementation (Lengnick-Hall et al., 2009). Most organizational strategy research offers some rationale to account for performance differences across organizations or to account for strategic differences that presumably have an impact on organizational performance (Barnett & Burgelman, 1996). SHRM is defined as the pattern of planned HR deployments and activities intended to enable an organization to achieve its goals (Wright & McMahan, 1992).

Organizational learning refers to the process of developing new knowledge and insights derived from the common experiences of people within the organization (Slater & Narver, 1995). Organizational learning is described as an important process that expands the organization's ability

DOI: 10.4018/978-1-5225-2255-3.ch377

to accomplish effective actions by improving its performance and results (Chiva & Alegre, 2009). Organizational learning includes the acquisition, dissemination, and use of knowledge (Argote, McEvily, & Reagans, 2003). Organizational learning is an extremely useful process for generating new ideas (Fernandez-Mesa & Alegre, 2015). Knowledge-sharing behavior positively mediates the relationships between organizational learning and organizational innovation and between KM and organizational innovation in the learning organizations (Kasemsap, 2014b).

Organizational policy perspectives can promote both SHRM and e-HRM toward increasing organizational learning, KM, and competitive advantage by encouraging the effective coordination and partnerships among organizations and combining employees' learning and development opportunities available to employees through modern learning technologies. Executives and HR managers should organize particular emphasis on employees' learning and development by implementing SHRM and e-HRM. The establishment of SHRM-related learning and development is the necessary component of organizational learning and KM strategies in modern organizations.

FACETS OF STRATEGIC HUMAN RESOURCE MANAGEMENT, ORGANIZATIONAL LEARNING, AND KNOWLEDGE MANAGEMENT

This section emphasizes the concept of SHRM; the concept of e-HRM; the importance of SHRM in modern organizations; and the current trends of organizational learning and KM in modern organizations.

Concept of Strategic Human Resource Management

With respect to the integration of HR issues in strategic decision making, the different levels of integration can be considered (Golden & Ra-

manujam, 1985). HRM is present at the highest management level and is crucial to organizational strategy (Bennett, Ketchen, & Schultz, 1998). Connecting HRM and strategic decision making improves organizational performance (Huselid, 1995). HRM has an added value in terms of influencing organizational performance (Liu, Combs, Ketchen, & Ireland, 2007). Stakeholder interests and contextual factors exert an influence on HRM policy choices (Guest, 1987).

In the SHRM literature, scholars focus on strategic outcomes, such as organizational performance (Becker & Huselid, 1998), strategic alignment (Schuler & Jackson, 1987), and competitive advantage (Wright, Dunford, & Snell, 2001). SHRM is defined as the significant activities affecting the behavior of individuals in their efforts to meet the strategic needs of the business (Schuler, 1992). SHRM implies that HR objectives have to be chosen in accordance with the general strategy of organization (Schalk et al., 2013). SHRM not only requires vertical alignment with an organization's business strategy, but each business activity also needs to be aligned with other HR activities (Lepak, Liao, Chung, & Harden, 2006).

This section is dealing with the concept of SHRM and the next section is dealing with the concept of e-HRM. SHRM is the strategic practice of attracting, developing, rewarding, and retaining employees with the important goal of increasing various benefits to both employees as individuals and organization as a whole.

Concept of Electronic Human Resource Management

The studies of electronic human resource management (e-HRM) began around 1995 (Strohmeier, 2007). Ruël et al. (2004) defined e-HRM as a way of implementing HRM strategies, policies, and practices in organizations through the conscious and directed support of and with the full utilization of the Internet. Strohmeier (2007) defined e-HRM as the application of information technology (IT) for both networking and supporting the interaction

of at least two individual or collective actors in their shared performing of HR activities. HR staff with substantial e-HRM implementations need the increased competency in the knowledge of business, functional HR delivery, and technology expertise (Bell, Lee, & Yeung, 2006).

Developing value from e-HRM should be possible if the organization utilizes e-HRM to acquire and develop superior human capital and to produce organizational knowledge, social networks that promote information sharing, and organizational processes that produce innovative responses in competitive markets (Marler, 2009). Large companies increasingly are turning to data mining to help identify and retain their qualified talents regarding talent management (Bondarouk, 2014). Data mining is the computational procedure of pioneering schemes in the large data sets regarding methods at the integration of artificial intelligence, machine learning, statistics, and database systems (Kasemsap, 2015a). Talent management introduces new strategic goals to streamline hiring and leadership succession processes (Kasemsap, 2016a).

This section is dealing with the concept of e-HRM and the next section is dealing with the importance of SHRM in modern organizations. With the advent of the Web 2.0, e-HRM can meet the challenge of becoming strategic, flexible, customer-oriented, and cost-effective by applying IT. Regarding strategic management, e-HRM can lower administrative costs, increase productivity, expedite response times, improve decision making, and enhance customer service toward improving all aspects of HRM in modern organizations.

Importance of Strategic Human Resource Management in Modern Organizations

Lengnick-Hall et al. (2009) indicated that SHRM involves three major stages (i.e., industrial organizational (I/O) economic perspective, resource-based view (RBV) perspective, and strategic evolution perspective). The I/O eco-

nomics perspective focuses on fit between HR practices and business strategy. Industry characteristics define the performance potential for companies based on the industry in which they operate and then within an industry, a firm's strategic positioning determines the extent to which it successfully competes to achieve competitive advantage.

The RBV perspective focuses on what and why HR resources and bundles lead to positive organizational outcomes (Lengnick-Hall et al., 2009). HRM can be strategic either as a specific capability or as instrumental in developing organizational resources (e.g., human capital and intellectual capital) that are rare and imperfectly imitable (Wright et al., 2001). Regarding strategic evolution perspective, the divergence between intended and implemented SHRM practices suggest the possibility that the outcomes of SHRM practice may vary depending on what decisions are made and what paths are taken during implementation (Marler & Fisher, 2013). Evolutionary strategic theorists view strategic responses to specific problems or opportunities that occur in the environment to be rationally bounded, which departs from the highly rationalized behavior (Gavetti & Rivkin, 2007).

This section is dealing with the importance of SHRM in modern organizations and the next section is dealing with the current trends of organizational learning and KM in modern organizations. SHRM is an essential business partner in organizational success, as opposed to a necessity for legal compliance or compensation. SHRM strategically utilizes organizational resources and talent within HR functions to make organizations more effective in the modern workforce. Organizational learning and KM allow for organizational employees to share knowledge and learn exactly what is relevant to their specific tasks toward encouraging human capital and knowledge creation. Organizational learning and KM also increase information sharing, communication, understanding, and the quality of decisions strategically made in modern organizations.

Current Trends of Organizational Learning and Knowledge Management in Modern Organizations

Organizational learning is conducted through either the exploratory or exploitative approach (Kim & Atuahene-Gima, 2010). Exploratory learning refers to the acquisition and learning of information and knowledge from outside current customer and competitor boundaries, and often involves experimentation and risk-prone projects (Kim & Atuahene-Gima, 2010). Ugurluoglu et al. (2013) stated that organizational learning is the procedure of increasing effective organizational movements through knowledge and understanding. Organizational learning is necessary in rapidly changing environments, through seeking new knowledge and the practical use of existing knowledge (Dayaram & Fung, 2014). Leaders of global businesses should organize information and communication technology (ICT) skills for organizational employees to enlarge their knowledge in global business (Kasemsap, 2014c).

Organizational learning positively affects export intensity (Bengtsson, 2004). A number of previous studies have viewed exporting as a process of knowledge accumulation during which company identifies and exploits opportunities abroad (Brouthers, Nakos, Hadjimarcou, & Brouthers, 2009). Knowledge renewal and exploitative learning regarding foreign markets increase exports (Balabanis, Theodosiou, & Katsikea, 2004) because firms that learn from their experience are able to export faster and with fewer mistakes. Firms effectively change by learning through the commitment decisions that they make to strengthen their position in the foreign market (Johanson & Vahlne, 2009). Organizational learning partially mediates the relationship between entrepreneurial orientation and performance and fully mediates the link between learning orientation and performance (Real, Roldán, & Leal, 2014).

The global economies thrive on cutting-edge knowledge, which drives research and organizational innovation in competitive environments (Kasemsap, 2016b). Organizational learning, HRM, and KM capability are related to improved organizational performance in modern organizations (Kasemsap, 2015b). Economic development is enhanced through the knowledge-based organizations to create new market and new industry platforms (Kasemsap, 2016c). KM is a functional set of behaviors, processes, and technologies that are designed for managing information more efficiently to improve learning, decision making, innovation, and other keys to business success (Kasemsap, 2016d).

Lifelong learning and KM have become a fundamental goal of education policies, both at a national and international level (Kasemsap, 2016e). Effective KM is the key driver of new knowledge and new ideas to the innovation process, innovative products, services, and solutions (Kasemsap, 2016f). IT and KM applications effectively improve the strategic tools for providing the direct link between customers and tourism organizations, thus encouraging the communication channels in global tourism (Kasemsap, 2016g). Organizational culture, organizational climate, and KM are positively related to job performance (Kasemsap, 2016h).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of SHRM, organizational learning, and KM will provide the potential opportunities for future research. In the knowledge economy, characterized by information, speed, and innovation, effective HRM is key to successful strategy execution. Human capital management (HCM) is an approach to employee staffing that perceives people as assets (human capital) whose current value can be measured and whose future value can be enhanced through organizational invest-

ment in the modern workforce. Communities of practice (CoPs) help promote a growing cycle of knowledge sharing activities that allow for the members to regularly meet, reflect, and evolve in the KM environment (Kasemsap, 2016i).

Organizations that embed the practices of human capital and competency across a range of HRM activities effectively create and develop a boundary spanning culture connecting with various organizational disciplines in the global knowledge economy (Kasemsap, 2016j). Cultural influences are changing dramatically, as organizational cultures are no longer dependent on local resources to formulate their characteristic tastes, preferences, and organizational behavior (Kasemsap, 2015c). The relationships among SHRM, organizational learning, KM, HCM, CoPs, and cross-cultural organizational behavior in the modern workplace will be the beneficial topics for future research directions.

CONCLUSION

This article highlighted the concept of SHRM; the concept of e-HRM; the importance of SHRM in modern organizations; and the current of organizational learning and KM in modern organizations. SHRM, organizational learning, and KM are the essential drivers of productivity growth and competitive advantage in the digital age. SHRM interacts with other departments within an organization in order to understand their goals and to create a strategy that aligns with organizational goals. Effective SHRM requires favorable organizational resources, such as the modern technologies (e.g., e-HRM, the Internet, and social media platforms) and the highly qualified employees through organizational learning, KM, professional development, and talent management.

Organizational learning and KM occur due to the interactions of organizational structure, strategy, environment, technology, and culture.

Organizational learning and KM become popular among organizations which are interested in facilitating competitive advantage, innovation, and effectiveness in the knowledge economy. SHRM, organizational learning, and KM are vital for modern organizations to sustain competitive advantage and promote organizational innovation. Regarding SHRM and e-HRM perspectives, organizational policies and agreements between employers and employees are the crucial perspectives of facilitating workplace learning in the effective KM environment. Promoting SHRM, organizational learning, and KM has the potential to enhance organizational performance and achieve strategic goals in modern organizations.

KEY TERMS AND DEFINITIONS

Human Resource: The resource that resides in the knowledge, skills, and motivation of people.

Human Resource Management: The process of hiring and developing employees so that they become more valuable to the organization.

Knowledge Creation: The formation of new ideas through the interactions between explicit and tacit knowledge in individual human minds.

Knowledge Management: The strategies and processes designed to identify, capture, structure, value, organize, and share an organization's intellectual assets to enhance its performance and competitiveness.

Learning: The measurable and relatively permanent change in behavior through experience, instruction, and study.

Learning Organization: The organization that obtains knowledge in order to survive in a rapidly changing environment.

Organizational Learning: The organization-wide continuous process that enhances its collective ability to accept, make sense of, and respond to the internal and external change.

Strategic Human Resource Management: The proactive management of the employees of an organization.

Technology, Learning Styles, Values, and Work Ethics of Millennials

Harish C. Chandan
Argosy University, USA

INTRODUCTION

Millennials represent people who were born between 1981 and 1997. In 2017, they are 20 to 36 years old. The Millennials are also called “Y” generation, digital natives, “net generation” or “me generation”. At present, the Millennials are university students and are entering the work force. The evolving technology has shaped their learning styles, values and work ethics. This chapter summarizes the influence of technology on learning styles, values and work ethics of Millennials. Implications of the different learning styles of the Millennials for the instructors’ teaching style, leadership style of university administrators and student services are discussed. The work ethics of Millennials are explored and implications for managerial and mentoring practices are discussed.

BACKGROUND

The entire adult population can be viewed as four generational cohorts – Silent (1928-1945), Baby Boomer (1946-1964), X (1965-1980), Y (1981-1997). The numbers in the parenthesis represent the range of birth years. There are slight variations in the birth years among different researchers (Pew Research Center, 2015).

Each generation has different values and viewpoints, which were shaped by their social, economic and political environment when they were growing up and their current level of responsibility. Different generational cohorts have different perceptions of each other and have different expectations. These perceptions are sometimes

based on positive and negative stereotypes reported in the popular press. These views are often not subjected to objective empirical scrutiny and there are variations within a generation (Macky et al., 2008). This generation gap can be a source of conflict and misunderstanding at the work place (Meriac et al., 2010).

TECHNOLOGY, NARRATIVE ABOUT MILLENNIALS, AND THEIR VALUES

Some of the major influences in a person’s development include peers, parents, popular culture, major political and social events. The differences in the social context and different shared life experiences of different generations lead to different beliefs, values and attitude towards work. The conventional view of the Millennials as narcissistic, self-absorbed, distrustful, anxious, cynical and lonely in the current competitive job-market may not be correct. There is no empirical evidence that the Millennials have a bad attitude. The Boomers’ perception of Millennials may reflect the old guard’s bias to new generations (Kowske, Rasch and Wiley, 2010). It may be that Millennials are adapting to the changing world that other generations are trying to resist (Ellin, 2014).

A lot of narratives about Millennials come from other generational cohorts and may reflect the biases of that generation (Twenge, 2009). The parenting styles, political events, social and cultural trends, technology and economic events during the time a generation is growing up contribute to the evolution of the psychosocial characteristics of a generation (Strauss and Howe, 1997; Howe

and Strauss, 2000). The differences in the social context and different shared life experiences of different generations lead to different beliefs, values, expectations, and attitude towards education and work. The popular press has both positive and negative stereotypes about Millennials, Table 1.

Millennials use texting more than e-mail as a regular mode of communication. They are comfortable with a wide variety of media including blogs, reviews and social networks to openly express their interests and feelings (Hershatter and Epstein, 2010). The Millennials watch less television and are not unduly influenced by the mainstream media. They are much more resistant to advertisements than previous generations (Ciminillo, 2005). Millennials are constantly adapting to the new forms of social media. The e-mail and Facebook may have become the grandpa's social media as the Millennials switch to Instagram. Millennials multitask using different technologies. Their multi-tasking behavior includes communicating with many people while playing Xbox (Putre, 2013; PwC, 2013). They are more connected digitally but may be socially isolated.

In today's hypermodern times, assembling sociality has become more challenging (Warde, 1999). The Millennials use social media to coordinate, stack or shift their social interactions to coordinate with personal schedules. Millennials migrate across a range of devices and platforms at on-line and off-line sites. Media are used for

entertainment and socializing (Botterill et al., 2015; Strauss and Howe, 2000; Hoover, 2009; PwC, 2008, Johnson Controls, 2010).

TECHNOLOGY AND LEARNING STYLES OF MILLENNIALS

Incorporation of technology in the classroom does enhance learning and is moderated by the student characteristics (Krentler and Willis-Flurry, 2005). As an example, the model of social learning environment as inquiry-based on cloud technology is being applied for enhancing the critical thinking skills and collaborative learning (Meepian and Wannapiroon, 2013). Multimedia and hypermedia Technologies affects positively on both learning in a content area and learning to use technology itself (Kinzer and Leu 1997). Technology can enhance literacy development, impact language acquisition, provide greater access to information, support learning, motivate students, and enhance their self-esteem (Boster et al., 2004; Tracey & Young, 2006).

Millennial students are used to instantaneous answers without much deliberate thought. This hinders the development of critical thinking. They do not realize that their lack of attention span or ability prevents them from focusing and contemplating the material deeply. They think that that they are not able to think critically due to lack of time. Millennials are comfortable learning through webinars, social media and virtual meetings. They are proficient users of productivity software for increased productivity at the workplace. Millennials find the right information and eliminate the unnecessary information (Ellin, 2014).

Raised by the overly involved 'helicopter parents', Millennials crave for immediate feedback, praise, attention and guidance. Many Millennials students lack critical thinking skills required for inductive and deductive reasoning (Monaco and Martin, 2007). They lack the original thought due to excessive reliance on the Internet. There is lack of concern for accuracy and validity of their

Table 1. Positive and negative stereotypes of millennials (Source: Twenge and Campbell, 2008)

Positive Stereotypes	Technology and Social media savvy, Multi-tasking, Digitally connected, Confident, Self-expressive, Liberal, Upbeat and Open to change, Civic minded with a sense of both local and global community
Negative Stereotypes	Narcissistic, Sense of entitlement, Coddled, Self-promotional, Opinionated, Whiny and Needy, Seek constant feedback and immediate gratification, Lack of diligence, Poor task performance and shirking behaviors

research sources. They are inclined to trust peer opinion and public consensus without verification (Hershatter & Epstein, 2010). Millennials need to practice critical thinking through meta-cognition, i.e. they need to be aware of what they are thinking and how they are thinking. In other words, they need to be able to verbalize the steps involved in solving a problem. Millennials need to be engaged with co-operative learning exercises and need help with analyzing their own learning strategies (McGlynn, 2005).

One has to recognize the students' generational characteristics and learning style and match it with the teaching style of instructors (Benfer and Shanahan, 2013). The Millennials thrive on working collaboratively in a flexible and open work or classroom environment. At Syracuse University, a collaborative classroom where new infrastructure is designed to promote collaborative, active learning is replacing the traditional classroom. The collaborative classroom features 10 interconnected LED monitors, reconfigurable tables, mobile whiteboards, dual overhead projectors, and a high tech teaching station. The classroom is designed for students to explore their course material in ways that are not possible in traditional classrooms. Instructors design their classroom activities to foster team-based learning (Syracuse Engineer, 2015).

Being technology savvy, the Millennials' educational expectations, socialization characteristics and learning styles are different as compared with previous generations. This requires changes in the educational programs, student services, and instructional strategies (Lowery, 2004). Universities and Colleges are redesigning student services and educational facilities including textbooks, library services and teaching methods to best serve the Millennials. Millennials prefer flexibility and mobility to learn in their own time and on their own terms. Millennials do multi-tasking, appreciate experiential learning, active engagement and prefer teamwork (Oblinger and Raines, 2002).

Freshmen retention is a critical component to the academic and financial success of an educa-

tional institution (Tinto, 2009). The persistence and retention of the Millennial freshmen college students is a challenge (Rickes, 2009). About 75% of the freshman students who do not return for sophomore year, more than 60% will not return to the same institution (Burshong, 2009). To improve the freshman retention for Millennials, universities need to focus on four new strategies including freshman focused activities, helping with effective study skills, more supportive instructor-student relationship and offering academic advisement support. The collaborative and interactive learning environment, ongoing academic guidance, study and time management skills development help a social and academic transition for the freshman students (Turner and Thompson, 2013). Universal design in learning and instruction helps with furthering educational goals for students. This leads to better learning outcomes and educational success (Much et al., 2014; Palmer, 2015).

TECHNOLOGY AND WORK ETHICS OF MILLENNIALS

For the first time in history, four distinct generations are coexisting in the work force—Millennials, Generation X, Baby Boomers and Traditionalists, Table 2 (PRC, 2015).

The *multi-dimensional work ethic profile* (MWEP) is a 7-dimensional construct and is defined as set of beliefs and attitudes reflecting the behavior at work including centrality of work, self-reliance, hard work, leisure, morality/ethics, delay of gratification and wasted time (Miller et al., 2002). Pogson et al. (2003) used MWEP to examine differences in work ethic as a function of one's career stage and found that differences in various dimensions of work ethic exist as a function of career stage. The limitations of this study were that the generational differences were confounded with age/career stage and the measurement equivalence of MWEP across the three career stages was not tested. Meriac et al., 2010 measured the generational differences in work

Table 2. Characteristics of four generations at work

Generation	% of Work Force	Characteristics at Work
Millennials (1981-1996)	27.7	Technology savvy, Respect for diversity, Socially conscious, Confident, Optimistic, Achievement oriented
Gen X (1965-1980)	19.8	Entrepreneurs, Self-reliant, Realist, Results-oriented, informal, fun,
Baby Boomers (1946-1964)	26.4	Workaholics, More conventional, Competitive, Optimistic, Personal gratification
Traditionalists (1928-1945)	13	Respect for rules, Conformity, Loyal, Hard work, Frugal

ethic using MWEP and examined the measurement equivalence across the three generational cohorts – Baby Boomers, Generation X and Millennials. It was found that the Millennials differ from other generations on several dimensions of the MWEP. However, the lack of measurement equivalence in several comparisons indicated that the different generations interpret the item content in the survey differently (Meriac et al., 2010).

From managerial standpoint, it may be more important to focus on learning about what the Millennials' values and attitudes regarding work are and not focus on the relevance of the generation differences. Comparing work ethics for different generations at a given time has several complexities including the effect of age, career-stage and applicability of the instrument used to measure the different generations.

Seven distinct characteristics have been identified for the Millennials in the workplace including *technological savvy*, *collaborative creativity*, *multi-tasking*, *work-life balance*, *social responsibility*, *education*, *diversity*, *open to change*, (Bannon et al., 2011; Innovation book). Each of seven characteristics has managerial implications in terms of mentoring and managing Millennials.

Being *technological savvy* includes workplace mobility, wireless devices, texting, and connected on social networks. At work, Millennials expect to have access to mobile and portable technologies. Millennials can positively contribute to the transformation of information and communication technologies to virtualization including cloud computing. Virtualization eliminates the need for

back-up copies of data on real storage devices. Cloud computing enables the storing of data for clients and employees. Companies can use the technology savvy characteristic of Millennials for learning new skills and training them through on-line simulations and case studies including new employee orientation, customer relations and ethical behavior. Their social habits include social networking, connecting, talking, sharing, tagging and creating and distributing content. Firms need to exploit the business advantages of social networking to better communicate and understand their Millennial employees, customers and other stakeholders.

Millennials are comfortable building relationships online. According to Mark Zuckerberg, "People have really gotten comfortable not only sharing more information and different kinds, but more openly and with more people. That social norm is just something that has evolved over time". The Face book founder Mark Zuckerberg was born in 1984 and is a Millennial. (Mossberg and Swisher, 2010).

Social media is used within and outside a company. Companies can incorporate social networking into the internal communication channels. Outside a company, the use of social media can help with company-customer, recruitment and obtaining background information on job applicants. Within a company, employees can share their organizational experience to share a story. In some cases, employees can intentionally expose the organizational issues and practices to resist organizational control. IBM encourages

employees to exchange ideas through blogs, and online communication. It promotes a dialogue between their partners, clients and other stakeholders. IBM employees use social media to informally communicate with other employees, managers and leaders on internal social media. BBC limits employee's social media use and has a clear social media policy where BBC-related photographs, offensive comments and videos are considered a disciplinary offense. Millennials perceive higher person-organization fit (POF) for a company with organizational policies supporting employees' social media use (Cho et al., 2013). Sharing information on-line can involve some work-related transgressions like blogging or tweeting negatively about their own company. Millennials need to be coached regarding social media policy of the company and information confidentiality.

The *collaborative creativity* characteristics of Millennials' is reflected in their preference for working collaboratively in a flexible and open work environment. Millennials are very comfortable with *multi-tasking*. They are able to process several incoming stimuli simultaneously and are excellent at multitasking. They are able to take in large doses of information from multiple sources simultaneously.

Millennials have benefited from playing video games in terms of decision-making, problem solving and thinking on their feet. Video games force an individual to analyze the options available and react quickly. Video games increase manual dexterity, eye-hand coordination and speed up neural pathways (Shotton, 1989). Millennials benefit from video games in terms of motivation creativity and cognitive skills as games aspire players to conquer a level to reach more difficult level. Millennials have developed hypertext minds that allow them to gather information rapidly from multiple sources and make connections between various sources of data.

The fourth of the seven characteristics of the Millennials is *work-life balance*, which is a big concern for them. They believe that the quality

of their work is more important than the number of hours spent in the traditional office. Flex Time is the preferred working mode for Millennials. This has a potential to transform the traditional nine-to-five office schedule for corporations to a more elastic timeframe. In addition, it has already transformed the parental leave policy. Facebook joined tech companies Amazon, Netflix and Microsoft Corp. in extending parental leave. In doing so, they are addressing the perception that today's workplace culture is incompatible with family and personal life. Facebook is extending its parental leave policy to four months paid time off for all employees around the world (Lori Matloff Goler, Head of human resources at Facebook, WSJ, 2016). A high task variety, high task identity, and a moderate level of both received interdependence and task significance are recognized as common job characteristics of knowledge workers across generations (Hernaus and Poloski, 2014).

Many Boomers expect that the Millennials will 'pay their dues' and 'earn respect'. Millennials want to be respected and valued for what they contribute, not for how long they have been with the organization (Deloitte, 2009). When Boomers see that the Millennials' do not have the same workaholic approach, they doubt the Millennials' ability to fit into the existing workgroup and culture (Expectancy theory) and demean them (Myers and Sadaghiani, 2010).

Millennials get bored easily and dislike menial tasks. They expect to move ahead quickly based on skills rather than experience (Eiser, 2009). Millennials will likely to want to work fewer hours (Deal, Altman and Rogelberg, 2010). They want their employers to be socially and environmentally conscious. They want meaningful relationships with clients and peers. They prefer flatter organizational structures (Shaikh, 2010). Millennials prefer brief communications with interactivities. They prefer webinars that entertain and educate (Dorsey, 2010).

A majority of the Millennials says that the older generation's work ethic and moral values are better than their own generation (Pew Research

Center, 2010). A lot of popular literature exists on perceptions about Millennials' work related attitudes and values, but there is limited empirical scientific data on comparing work ethics of different generational cohorts (Mackay et al., 2008).

The organizations have to develop strategies for managing the interactions between generations including mentoring, team working, and the design of the physical and virtual workplace to maximize productivity. The changing pattern of work and life dictate that organizations have to adapt their organizational culture to meet the demands and expectations of new generations in the workplace (Bannett, 2012).

The differences in work-related attitudes and values among different generations can be a source of misunderstandings and conflict in the workplace (Twenge and Campbell, 2008).

FUTURE RESEARCH DIRECTIONS

There is very little research available about the most effective way of teaching Millennials. More research is needed to improve retention of Millennial students in colleges by updating the educational curriculum in a way that promotes a collaborative and interactive student-centered environment (Toohey et al., 2016). The role of multi-tasking on the critical thinking skills for Millennials needs to be understood better. Instructors have to be retrained for student centered learning.

The personality traits do not consistently predict the task performance and shirking behaviors like cyber loafing. Based on cognitive psychology, the performance on the Cognitive Reflection Test (CRT) is a good indicator of task performance and shirking behaviors (Corgnet et al., 2015). Research is needed to understand the role of CRT in understanding the cyber loafing phenomenon among the Millennials.

Managers need to question their assumptions about the Millennials, encourage open communication, provide positive feedback frequently and provide negative feedback with discretion

(Keene and Handrich, 2010). Research is needed to learn about effective ways of providing feedback and mentoring the Millennials. More research is needed about how organizations would benefit by bringing social media platforms (e.g. Yammer) into their internal communication strategy and increase employee involvement and commitment. Inter-generational mentoring may be a good way to enhance communication and understanding between the generations. More research is necessary about the effectiveness of inter-generational mentoring. We need to understand the Millennials as they are and not through the lens of the other generations' perceptions.

CONCLUSION

The Millennials are redefining what it means to be an individual in today's complex, connected, global and competitive society. Currently, Millennials are the largest generation in United States. Half of them are already in the workforce. Through the increasing use of ICT technologies, Millennials are reshaping the businesses, organizations, university student services and teaching practices including student-centered and collaborative learning. Firms have to figure out how to effectively engage the Millennials to achieve productivity gains, higher job satisfaction, and lower turnover rate. To improve retention, organizations have to create an open workplace culture, frequent communication, flexible work styles, skill-based compensation and career structure, career development and work-life balance opportunities that resonate with the aspirations of the Millennials. Teachers, leaders, managers and human resource professionals need to understand the Millennials' use of technology to enable them to update the teaching, student services and organizational practices to resonate more with the Millennials who represent the future of the society where one needs skills to go beyond the information age to move into the conceptual age where the big picture and innovation are essential.

KEY TERMS AND DEFINITIONS

Critical Thinking: Critical thinking is a combination of skills including skepticism (questioning everything) evidence-based reasoning and not emotional response, self-awareness about assumptions and biases, and open-mindedness about alternative explanations.

Cyber -Loafing: A type of shirking behavior at work that involves using the Internet at work for personal use while pretending to do legitimate work.

Generational Cohorts: The entire adult population can be viewed as four generational cohorts – Silent (1928-1945), Baby Boomer (1946-1964), X (1965-1980), Y (1981-1997). The numbers in the parenthesis represent the range of birth years.

Millennials: Millennials represent people who were born between 1981 and 1997. In 2017, they are 20 to 36 years old. The Millennials are also called “Y” generation, digital natives, “net generation”, Trophy generation or “me generation”.

Work-Life Balance: A concept that promotes a balance between work and leisure, career development and lifestyle activities including family, health, spiritual development and pleasure.

Cuckoo Search Algorithm for Solving Real Industrial Multi-Objective Scheduling Problems

Mariappan Kadarkarainadar Marichelvam
Mepco Schlenk Engineering College, India

Mariappan Geetha
Kamaraj College of Engineering and Technology, India

INTRODUCTION

Scheduling is an essential task in our day-to-day life that helps us to shape up our daily activities. The arrival and the departure of airplanes have to be scheduled in an airport. The class hours and the examinations are scheduled in the schools and Universities. Schedules are prepared in industries too. Today, industries need meticulous planning and scheduling to meet the customer demands. Due to globalization and liberalization the attributes of the customers have changed. Hence, industries ought to satisfy them by improving the quality, reducing the price and despatching the goods on time. Scheduling is one of the most important decision making processes. Scheduling is defined as a process of allocating resources over time to perform the assigned tasks effectively (Baker & Trietsch 2009). The machines, equipment, facilities, computers and operators are the important resources in all organizations. Effective scheduling leads to improve the productivity, reduce the inventory, improve the production efficiency, minimize the production time and cost and hence increase the efficiency of the production system. Different types of scheduling environments were addressed by Pinedo (1995). Among them the hybrid flow shop (HFS) environment plays a vital role as many industries resemble it. The HFS has also been called as a flexible flowshop, multiprocessor flow shop, flexible flow line, flow shop with multiple processors or a flow shop with

parallel machines by Ribas et al. (2010). Different operations are performed in different machines in a simple flow shop. The HFS consists of a set of production stages in which each stage has multiple parallel machines. An HFS consists of both the flow shop and parallel machine environments. The parallel machine scheduling system involves the scheduling of a set of immediately available jobs, each on one of the parallel machines. The simple flow shop scheduling system is described as the sequencing of a set of immediately available jobs through each of the ordered work centers. There are two or more work centers in this system but only one machine at each work center. In the HFS, some stages may have only one machine. But, at least one stage should have two or more parallel machines. The machines may be identical, uniform or non-uniform. Some of the jobs may skip some of the stages in the HFS environment. The jobs flow in unidirectional in the HFS environment. Though many researchers have addressed the HFS scheduling problems for more than 40 years, only a few researchers have addressed the real-industrial scheduling problems with multiple objectives which are conflicting naturally with each other. Hence, in this paper a bi-objective HFS scheduling problem is considered. The objective is to minimize the makespan and mean flow time. The layout of an M-stage hybrid flow shop environment is given in figure 1.

Hoogeveen et al. (1996) proved that a two-stage hybrid flow shop scheduling problem is NP-hard

DOI: 10.4018/978-1-5225-2255-3.ch379

Figure 1. Layout of the hybrid flow shop environment

in the strong sense even if there is only one machine on the first stage and two machines on the second stage. Hence, we cannot find the optimal solutions for these problems in a reasonable time. As the hybrid flow shop scheduling problems are NP-hard problems, the problems cannot be solved by exact algorithms. Researchers proposed many heuristics and meta-heuristics to solve the hybrid flow shop scheduling problems. Cuckoo search algorithm is a recently developed meta-heuristic algorithm. In this chapter, the cuckoo search algorithm is proposed to solve the multi-objective hybrid flow shop scheduling problems.

BACKGROUND

Hybrid flow shop scheduling problem was first proposed by Arthanari and Ramamurthy (1971). Researchers have developed many heuristics and meta-heuristics to solve such problems and to obtain optimal or near optimal solutions with considerably less computational time. Lee and Vairaktarakis (1994) proposed heuristics to minimize makespan for hybrid flow shop scheduling problems. Riane et al. (1998) proposed efficient heuristics to minimize makespan for a three-stage flow shop problem. Brah and Loo (1999) proposed a heuristic for flow shop scheduling problems with multiple processors. Oğuz et al. (2003) also proposed some heuristics to solve multiprocessor

task scheduling in a two-stage flow shop scheduling problems.

Recently, many meta-heuristics have been widely applied for solving the hybrid flow shop scheduling problems. Engin and Döyen (2004) proposed an artificial immune system algorithm for solving the hybrid flow shop scheduling problems to minimize the makespan. Yang et al. (2004) applied the tabu search simulation optimization algorithm to solve the multiprocessor flow shop scheduling problems. They applied the algorithm to solve the scheduling problem of a ceramic capacitor manufacturing company. Oğuz and Ercan (2005) have presented a genetic algorithm for the hybrid flow shop scheduling problems with multiprocessor tasks. They used a local search algorithm as a decode method to obtain the objective function value. They also proposed a new crossover operator in their work. Ruiz and Maroto (2006) have also addressed a genetic algorithm that consists of various new crossover operators to minimize makespan for the hybrid flow shop scheduling problems. The sequence dependent setup time and machine eligibility were considered by them. Ying and Lin (2006) developed an ant colony system (ACS) approach to solve the hybrid flow shop scheduling problems. Alaykíran et al. (2007) also proposed an improved ant colony optimization algorithm to minimize makespan for multistage hybrid flow shop scheduling problems. Jungwattanakit et al.

(2008) formulated a 0–1 mixed integer program for hybrid flow shop scheduling problems with unrelated parallel machines. They have developed a polynomial heuristic and also a genetic algorithm to minimize makespan and total number of tardy jobs. Tseng and Liao (2008) proposed a particle swarm optimization algorithm to solve the hybrid flow shop scheduling problems to minimize makespan. Jungwattanakit et al. (2009) compared the performance of three different meta-heuristic algorithms (genetic algorithm, tabu search and simulated annealing) to minimize the convex sum of makespan and the number of tardy jobs for flexible flow shop problems with unrelated parallel machines. Jouglet et al. (2009) proposed a memetic algorithm to minimize makespan for the hybrid flow shop scheduling problems. They used a constraint programming based branch and bound algorithm as the local search in their work. Kahraman et al. (2010) solved the multiprocessor task scheduling in multistage hybrid flowshop using a parallel greedy algorithm approach. Khalouli et al. (2010) suggested an ant colony optimization algorithm for the hybrid flow shop scheduling problems to minimize the sum of the total earliness and tardiness. Rashidi et al. (2010) presented an improved multi objective parallel genetic algorithm for hybrid flow shop scheduling with unrelated parallel machines to simultaneously minimize the makespan and the maximum tardiness. Ruiz and Vázquez-Rodríguez (2010) presented a detailed literature review on exact, heuristics and meta-heuristics methods that have been proposed for the hybrid flow shop scheduling problems. They reported the different industries that resemble the hybrid flow shop scheduling environment and pointed out that only a very small percentage of works concentrated on real industrial scheduling problems. An efficient genetic algorithm was developed by Engin et al. (2011) to solve the hybrid flow shop scheduling with multiprocessor task problems. Behnamian and Ghomi (2011) solved the hybrid flow shop scheduling problems to minimize makespan and total resource allocation costs using genetic al-

gorithm hybridized with variable neighbourhood search. The machine and resource dependent processing time was considered by them. They have developed some random problems and compare their results. Wang et al. (2011) proposed a simulated annealing algorithm for the hybrid flow shop scheduling problems to minimize the makespan. Marichelvam and Prabaharan (2012) applied the bat algorithm for solving the realistic hybrid flowshop scheduling problems to minimize makespan and mean flow time. Mousavi et al. (2013) also proposed a simulated annealing algorithm hybridized with some local search methods to minimize the makespan and total tardiness on a hybrid flowshop environment. Marichelvam et al. (2013) solved the hybrid flow shop scheduling problems using the bat algorithm. Marichelvam et al. (2014) also developed a discrete firefly algorithm for the multi-objective hybrid flowshop scheduling problems. Makespan and flow time are the objective functions considered by them. Marichelvam and Prabaharan (2014) developed an improved hybrid genetic scatter search (IHGSS) algorithm for multistage hybrid flow shop scheduling problems with missing operations. They hybridized the genetic algorithm and scatter search algorithm to minimize the makespan. Marichelvam and Geetha (2014) addressed the tri-objective multistage hybrid flow shop scheduling problems. They solved the problems using the discrete firefly algorithm.

Cuckoo search algorithm is one of the recently developed population-based meta-heuristic algorithms, developed by Yang and Deb (2009). Layeb (2011) applied the quantum inspired cuckoo search algorithm for solving the knapsack problems. Valian et al. (2011) developed an improved cuckoo search algorithm for solving the global optimization problems. Gherboudj et al. (2012) proposed a discrete binary version of cuckoo search algorithm for solving the 0-1 knapsack problems. Layeb and Boussalia (2012) applied a novel quantum inspired cuckoo search algorithm for bin packing problem. Marichelvam (2012) proposed an improved hybrid Cuckoo Search metaheuristics algorithm for permutation flow shop scheduling problems

to minimize the makespan. Basu and Chowdhury (2013) proposed the cuckoo search algorithm for solving the economic dispatch problems. Burnwal and Deb (2013) solved the scheduling optimization problems of flexible manufacturing system using the cuckoo search-based approach. Civicioglu and Besdok (2013) presented a conceptual comparison of the cuckoo search algorithm, particle swarm optimization, differential evolution and artificial bee colony algorithms. Gandomi et al. (2013) solved the structural optimization problems using the cuckoo search algorithm. Kaveh and Bakhshpoori (2013) steel frame design optimization problems using the cuckoo search algorithm. Ouyang et al. (2013) developed a novel discrete cuckoo search algorithm for spherical traveling salesman problem. Vo et al. (2013) applied the cuckoo search algorithm for non-convex economic dispatch problems. Yang and Deb (2013) developed a multi-objective cuckoo search for design optimization problems. Marichelvam et al. (2014) proposed an improved cuckoo search algorithm for solving the hybrid flow shop scheduling problems to minimize makespan. A Discrete cuckoo search algorithm was proposed by Ouaarab et al. (2014) for solving the travelling salesman problem. Yang and Deb (2014) presented the recent advances and applications of the cuckoo search algorithm.

From the above literature review, one can easily conclude that the applications of the cuckoo search algorithm to solve the multi-objective scheduling problems require further extensive studies. Hence, in this paper the cuckoo search algorithm is proposed to minimize makespan and flow time for multistage hybrid flow shop scheduling problems.

MAIN FOCUS

This chapter considers the hybrid flow shop scheduling problems. The objective is to minimize the makespan and mean flow time. Makespan is defined as the completion time of the last job in the production system. Makespan is a performance measure used to improve the efficiency of the production system. Mean flow time is defined as

the average time spent by the jobs in the production system. Reduction in mean flow time will result the reduction in work-in-process inventory. It also reduces the average response time. Hence, minimization of makespan and mean flow time are considered in this chapter. Marichelvam et al. (2014) proposed the mathematical model for the hybrid flow shop scheduling problems to minimize the weighted sum of makespan and mean flow time. The same mathematical model for the objective function of minimization of weighted sum of makespan and mean flow time is considered in this chapter. They considered several assumptions. The same assumptions are considered in this chapter also. The assumptions are:

- All n jobs are available at the beginning of scheduling.
- Each stage has infinite storage capacity.
- One machine can process only one job at a time.
- One job can be processed by only one machine at any time.
- For all the jobs, the processing times at each stage are known in advance and deterministic.
- Job set-up times are sequence-independent and are included in the job processing time of the jobs at the corresponding stage.
- Travel time between consecutive stages is negligible.
- Preemption is not allowed.

CUCKOO SEARCH ALGORITHM

Cuckoo search (CS) algorithm is a new nature-inspired metaheuristic algorithm developed by Yang and Deb (2009). Cuckoo search algorithm was inspired by the obligate brood parasitic behavior of some cuckoo species in combination with the Lévy flight behavior of some birds and fruit flies in nature. The breeding behaviour and the Lévy flights will be discussed in the following sections.

CUCKOO BREEDING BEHAVIOUR

Some of the cuckoo species lay their eggs in the nests of other host birds. The cuckoos often select the recently spawned nests instinctly. They may remove others eggs to increase the hatching probability of their own eggs. Some host birds can engage direct conflict with the intruding cuckoos. If a host bird discovers the eggs are not their owns, they will either throw these alien eggs away or simply abandon its nest and build a new nest elsewhere. Some cuckoos have evolved in such a way that female parasitic cuckoos are often very specialized in the mimicry in colour and pattern of the eggs of a few chosen host birds. This will reduce the probability of their eggs being abandoned. This also increases their reproductivity. Furthermore, the timing of egg-laying of some cuckoos is also amazing. The cuckoos often choose a nest where the host bird just laid its own eggs. In general, the cuckoo eggs hatch slightly earlier than their host eggs. Once the first cuckoo chick is hatched, the first instinct action it will take is to evict the host eggs by blindly propelling the eggs out of the nest. This will increase the cuckoo chick's share of food provided by its host bird. Moreover, a cuckoo chick can also mimic the call of host chicks to gain access to more feeding opportunity.

RULES OF CUCKOO SEARCH ALGORITHM

Based on the brooding behaviour of cuckoos, the basic steps of cuckoo search are described using the following three idealized rules/approximations:

1. Each cuckoo lays one egg (solution) at a time, and dumps its egg in a randomly chosen nest. That is, an egg represents a solution. As there is one egg in one nest, then it can be assumed that an egg is equivalent to a nest and a solution.
2. The best nests with high quality eggs/solutions will carry out to the next generation.

Here is the best means the solution with the best (minimum) objective values (for minimization problems).

3. The egg laid by a cuckoo can be discovered by the host bird with a probability P_a and a nest will then be built. That is to say, a fraction P_a of the n nests being replaced by new nests (with new random solutions at new locations).

For minimization problems the quality or fitness function value may be the reciprocal of the objective function. Each egg in a nest represents a solution and the cuckoo egg represents a new solution. Therefore, there is no difference between an egg, a nest and solution. The pseudo code of the cuckoo search algorithm is presented below.

```

Start
Objective function  $f(x)$ ,  $x = (x_1, x_2, \dots, x_d)$ 
Generate initial population of  $n$  host nests  $x_i$  ( $i = 1, 2, \dots, n$ )
While ( $t < \text{MaxGeneration}$ )
  Get a cuckoo randomly (say  $a$ ) by Lévy flights
  evaluate its quality/fitness  $F_a$  [proportional to  $f(x)$ ]
  Choose a nest among  $n$  (say  $b$ ) randomly
  if ( $F_a$  is better than  $F_b$ ),
    replace solution  $b$  by the new solution;
  end
  A fraction ( $P_a$ ) of worse nests is abandoned and new ones are built;
  Keep the best solutions (or nests with quality solutions);
  Rank the solutions and find the current best
end while
Post process results and visualization
End
  
```

When generating new solutions $x_a^{(t+1)}$ for a^{th} cuckoo a Lévy flight is performed using the equation (1).

$$x_a^{t+1} = x_a^t + \alpha s \otimes H(p_a - \varepsilon) \otimes (x_j^t - x_k^t) \quad (1)$$

where x_j^t and x_k^t are two different solutions selected randomly by random permutation, $H(u)$ is a Heaviside function, ε is a random number drawn from a uniform distribution, and S is the step size. On the other hand, the global random walk is carried out by using Lévy flights

$$x_i^{t+1} = x_i^t + \alpha L(s, \lambda), L(s, \lambda) = \frac{\lambda \Gamma(\lambda) \sin(\pi \lambda / 2)}{\pi} \frac{1}{s^{1+\lambda}}, (s \gg s_0 > 0). \quad (2)$$

Lévy flights essentially provide a random walk while their random steps are drawn from a Lévy distribution for large steps ($1 < \lambda \leq 3$). Here the step size vector L is drawn from the power-law distribution as given in equation (2).

LÉVY FLIGHTS

In nature, animals search for food in a random manner. In general, the foraging path of any animal is effectively a random walk because the next move is based on the current location and the transition probability to the next location. The direction of movement depends implicitly on a probability which can be modeled mathematically. The Levy flights model involve a lot of small steps, interspersed with occasional very large excursions. Yang and Deb (2013) have pointed out that the Lévy flights are a random walk whose step length is drawn from Lévy distribution. The foraging path is very important as the stopping points of a Levy flight are fractal (scale invariant is the main point here), and in complex ecosystems the distribution of food is also fractal. (i.e. there are some large

areas without food). To avoid spending too much time in such unproductive areas, animals need to develop search strategies that generate a fractal distribution of stopping points. Levy flights have this property. The turning points and the trajectory of the Lévy flights are presented in Figure 2. The cuckoo search algorithm consists of three parameters P_a , α , and λ . Among them the parameters P_a and α are very important to obtain better solutions. In the literature, these parameters of the cuckoo search algorithm are kept constant. But, in this thesis work, the parameters P_a , α , and λ are not kept constant. The parameters of P_a and α are determined by the design of experiments. The values used in the simulations are based on extensive parametric studies and the parameters would be $n=15$ to 40 , $\lambda=1.5$, and $\alpha=0.01 \cdot \text{abs}(\text{Ub}-\text{Lb})$, where Ub and Lb are the upper bound and lower bound, respectively, of the problem of interested.

SOLUTIONS AND RECOMMENDATIONS

In order to validate the performance of the proposed algorithm a real industrial scheduling problem is considered in this chapter. The scheduling problem of a leading furniture manufacturing is considered in this chapter. The furniture manufacturing company is one of the leading industries in Tamilnadu, India. The layout of the collaborative company is depicted in Figure 3. The number of stages are five and the number of machines in each stage are presented in Table 1 and the processing time of jobs is presented in Table 2.

To validate the performance of the proposed algorithm the results are compared with many other algorithms addressed in the literature. Mean relative deviation index proposed by Marichelvam et al. (2014) is used in this paper as a performance measure in this chapter. MRDI is one of the most important performance measures used in the scheduling literature. Lower MRDI will be the indication of better performance of the proposed algorithm. The MRDI is calculated using the

Figure 2. Turning points and trajectory of the Lévy flights

Table 1. Number of machines in each stage

Sl. No.	Stage	Number of Machines
1	Punching	5
2	Bending	8
3	Welding	5
4	Power pressing	3
5	Drilling	1

Table 2. Processing time of jobs (in seconds)

Stages → Jobs ↓	Punching	Bending	Welding	Power Pressing	Drilling
1.	39	28	0	0	0
2.	61	66	110	0	0
3.	10	17	52	0	0
4.	22	0	0	0	0
5.	35	60	0	0	0
6.	34	66	70	0	0
7.	42	0	0	0	0
8.	42	0	0	50	0
9.	34	250	30	0	0
10.	12	18	25	0	0
11.	0	0	0	10	0
12.	0	0	0	20	0
13.	52	90	0	0	0
14.	0	0	0	20	0
15.	0	0	0	42	0
16.	12	22	0	0	32
17.	0	0	0	8	0
18.	0	0	0	6	0
19.	0	0	0	10	0
20.	0	0	0	6	0

equation (3). The MRDI is comparison of different algorithms is presented in Table 3.

$$MRDI = \sum_{l=1}^R \frac{(Z^* - Z_{meta})}{Z^*} \times 100 / R \quad (3)$$

Where,

Z^* = best objective function value

Z_{meta} = objective function value obtained by the different algorithms

R = number of runs (20)

From the result table, it is concluded easily that the performance of the proposed cuckoo search algorithm is better than many other algorithms

addressed in the literature for the multi-objective real industrial scheduling problems. This indicates the effectiveness of the proposed algorithm.

1	Ant colony optimization algorithm	3.91
2	Cuckoo search algorithm	0
3	Genetic algorithm	2.23
4	Particle swarm optimization algorithm	1.56
5	Simulated annealing algorithm	2.77

FUTURE RESEARCH DIRECTIONS

In this chapter, the multi-objective hybrid flow shop scheduling problems are considered. However, many assumptions are made in this chapter. For instance, the setup time is not addressed in this chapter. Consideration of setup time and transportation time is a future research scope of this work. Consideration of due date related criteria such as earliness and tardiness would be another interesting scope of this research. The cuckoo search algorithm may also be applied for other optimization problems. The proposed algorithm might be hybridized with other algorithms.

CONCLUSION

The multi-objective hybrid flow shop scheduling problem is addressed in this chapter. A recently developed cuckoo search algorithm is proposed to minimize makespan and mean flow time for the hybrid flow shop scheduling problems. The algorithm is validated with a real industrial data. The performance of the proposed cuckoo search algorithm is compared with other algorithms such as ant colony optimization, genetic algorithm, particle swarm optimization and simulated annealing and proved to be better.

KEY TERMS AND DEFINITIONS

Cuckoo Search Algorithm: A recently developed meta-heuristic algorithm to solve the optimization problems.

Makespan: Makespan is defined as the completion time of the last job to leave the system.

Mean Flow Time: Mean flow time is defined as the average time spent by the jobs in the production system.

NP-Hard Problems: Non – deterministic polynomial time hard problems.

Scheduling: Scheduling is defined as a process of allocating resources over time to perform a collection of tasks.

The Trends and Challenges of 3D Printing

Edna Ho Chu Fang

University of Malaya, Malaysia

Sameer Kumar

University of Malaya, Malaysia

INTRODUCTION

3D printing is the new wave of technology advancement in the world of architecture, design and manufacturing. Also known as rapid prototyping, 3D printing is a type of additive manufacturing technology where a 3D object is created by laying down subsequent layers of material at the mm scale. 3D printers print objects by reading a CAD design file or by scanning an object (Sachs et al., 1992). Today, 3D printing is applied in various industries such as footwear, jewelry, architecture, engineering and construction, aerospace, dental and medical industries, education, consumer products, automotive and industrial design. Some claim that 3D printing will put an end to traditional manufacturing primarily since 3D printing imposes a tool-less process. Product parts can be specifically designed to avoid assembly lines, as well as ensuring maximum utilization of raw materials. In this article, the authors discuss the state-of-the-art of 3D printing its future direction.

BACKGROUND

In May 1980, Dr Kodama from Japan filed the very first patent application for Rapid Prototyping technology. Unfortunately, he did not file the subsequent full patent specification before the one year deadline after the application. Hence, in 1986, Charles (Chuck) Hull filed the first patent for stereolithography apparatus (SLA). He was the first to invent the SLA machine in 1983. After obtaining the patent, he went on to co-found 3D

Systems Corporation, which is one of the largest organizations operating in the 3D printing world today. During the mid-nineties, the 3D printing sector started to diverge into two specific areas. First, there was the high end of 3D printing, which saw the production of complex parts. These applications include the medical, aerospace, jewelry and automotive sectors. Then there was the lower end of the market, which saw a price war among many 3D printer manufacturers, highlighting improvements in speed, accuracy and materials.

In 2007, 3D Systems came up with the first 3D printer which was priced under \$10,000. The first commercial 3D printer was offered for sale in January, 2009. It was based on the RepRap concept, and came in a kit form. Makerbot Industries also developed commercial printers in April of the same year. 2013 saw Stratasys acquiring Makerbot. It was a year of significant growth and consolidation for 3D printing.

Materials for 3D printing were very limited during the early days of the technology. Today, there is an array of different types of materials available for choice.

The first step in 3D printing is to design the 3D digital model using a CAD program or scan the object with a 3D scanner. The model will then be 'sliced' into layers and converted into a printer-readable file. The printing material will be added one layer at a time.

Different materials are suited for different 3D printing technologies. Some 3D printers process powdered materials which utilize a light source to fuse layers of the powder together to make the desired shape. Others process polymer resin

materials and utilize a laser to solidify the resin in ultra thin layers. Another method is the jetting of fine droplets using materials and a binder to fix the layers. One of the most commonly used 3D printing technology is the stereolithography (SLA) technology. This technology utilizes photocuring resins as raw material. New resins that are being developed will combine transparency, heat resistance and toughness.

The second commonly used technology is called 'Fused Deposition Modeling', as invented by Scott Crump, a co-founder of Stratasys Inc. The FDM technology uses thermoplastic resins as raw materials. It is the simplest 3D additive manufacturing technology, in which the thermoplastic resin softens when heat is applied. The third type of technology is called 'Selective Laser Sintering (SLS)'. This builds objects by using a laser to fuse together layers of a mixture of different powdered raw materials. The fourth type of technology is called 'Multi-jet modeling (MJM)'. Objects are built up from the layering of powder through an inkjet-like print head that also sprays a binder solution to glue the required granules together. The raw materials associated with this type of technology are sand mold or nylon resins.

THE TECHNICAL ISSUES OF 3D PRINTING

3D printing has revolutionized our society from providing medical advances; to scalable production of everything from product parts to buildings. There are, however, many issues that accompany this technology. Two main issues of 3D printing are the technical problems and the controversies. This section will be divided into two parts. Part one presents the technical problems of 3D printing, while part two presents the controversies of 3D printing.

As 3D printing is getting more widespread, the issue of its quality is always being questioned. In 3D printing, the quality of the printed object is linked to the printing speed; and the printing

speed is linked to the raw materials' thermoplastic properties. Different raw materials are supposed to be printed at different speeds. To ensure a beautifully printed object, the speed of printing has to be just right – not too slow and not too fast either.

Some of the common printing problems are warping, stringing, gaps in the top layers, under-extrusion, over-extrusion, pillowing, layer-misalignment, elephant foot, etc. Furthermore, the raw materials that can be used for 3D printers are still rather limited. Presently, most of the commercial 3D printed products consist of one single material. The idea of printing electronic goods such as smart phones is already being researched but not yet foreseeable. The tough challenge here is to add different types of materials that fulfill their functionality to make up various parts of an electronic component.

Last but not least, 3D printing requires post-processing. An additive manufacturing (AM) machine cannot add finishing touches to the printed object. It requires a manually intensive process. The printed objects will still have to undergo post-printing processes such as friction-weld, paint, sand, rivet and so on.

The Controversies of 3D Printing

The controversies surrounding 3D printing include infringement of intellectual property laws, fabrication of weapons and drugs for crime purposes, compliance with FDA safety standards and ethical considerations.

Intellectual Property Laws

Online platforms such as GrabCad and Thingiverse provide users with the CAD design files needed for 3D printing. Registered users can download, upload, design and modify a 3D model on these online platforms. Infringement of copyright laws happens through the way users obtain the CAD design files. They either: (1) create an object design file; (2) modify an existing design; (3) scan the object (Mendis & Secchi, 2015). The main ques-

tion here is whether a CAD file can be protected under the copyright law. Firstly, for a design to be eligible for protection, it has to qualify as a literary work. Many arguments are in favor of the notion that a CAD file is not a type of computer program (literary work), hence it is not eligible for protection under the copyright law.

Rideout (2012) asserts that CAD files cannot be categorized as copyrightable software in the USA because they are just “triangular representations of a 3D object”. Unlike computer programs, the CAD files do not control the way 3D printers operate. He justifies that a 3D design file isn’t a literary work and is more likely to be considered under “graphic and sculptural works”. Then again, another issue will be raised if 3D designs were to be considered as sculptural works. Art works have their own set of copyrights. Apparently, a 3D model does not infringe copyright laws if the CAD file is used to create an object for use and not as an artwork. This is showcased in the example of Andrew Ainsworth, a props maker who in the film *Star Wars*, printed the Stormtroopers’ white helmets and justified that it was for use and not as an artwork. The court ruled in favor of Ainsworth.

Whilst the USA stands by the notion that a CAD file cannot be protected under the copyright law, the UK believes that a CAD file could be protected. As for now, the copyright status of CAD design files remains unclear.

Fabrication of Weapons or Drugs for Crime Purposes

3D printing provides users with countless possibilities. As much as it can be used for good purposes, it can also be misused when it falls into the hands of people with ill intentions. Anyone with sufficient modal can own a 3D printer and start printing guns or illegal drugs at the comfort of their homes. They are only limited by the costs and technological capabilities of the printers, as well as the availability of the raw materials.

Ever since Cody Wilson, a law student who became the first man to ever print a gun called

‘the Liberator’ from a 3D printer, firearms enthusiasts are constantly modifying gun designs to come up with more durable guns made from a combination of 3D printed materials and parts taken from traditionally manufactured guns. 3D printed guns pose threats to the society because metal detectors cannot detect them.

Generally, the United States allows its citizens to own guns though each state has its own regulatory laws regarding gun ownership. For example, in California, people with a negative track record or people with mental illness are prohibited from owning firearms. 3D printing enables almost anyone to possess a firearm through self-manufacturing.

The group of people who called for firearms to be banned in the States fear that 3D printed guns might be used for crimes or mass shootings. Even if the government does ban 3D printed guns, the technological advances in firearm printing will not stop there as it is part of the European history and culture to own guns.

While owning a firearm is legal, how about owning a gun design file? The province of New South Wales of Australia recently enacted a law that bans gun design files. The amendment made to the Firearms Act 1996 states that possessing 3D digital blueprints for manufacturing firearms is a crime punishable with a penalty of up to 14 years in jail. Individuals who possess digital gun blueprints for research purposes are legally exempted from the law.

The legal stand of manufacturing own firearms differ amongst countries all over the world. Some countries such as Australia and Japan have banned the possession of gun design files, while the US does not. Currently, making own firearms is legal in the US as long as it is intended for personal use only and not for commercial purposes.

Manufacturing of Illegal or Counterfeit Drugs

As with the printing of weapons, criminals might misuse 3D printing to manufacture illegal or

counterfeit drugs. Professor Lee Cronin and a team of 45 researchers at Glasgow University are researching on additive manufacturing technology that would allow drugs to be produced through 3D printing. It was discovered that bathroom sealant which acts as the “ink” for creating reaction chambers was a suitable raw material for the 3D printer. The printer can inject “chemical inks” that would create more complex molecules through a series of reactions (“3-D Printing: The Potential Implications and Challenges for Law Enforcement”, 2015).

Cronin stated that almost all drugs are made of the similar components of oxygen, carbon, and hydrogen with vegetable oils and paraffin. He foresees that in the future, people will be able to download drug recipes from online platforms and use 3D printers to produce medicines at their homes. When this happens, 3D printed drugs might not just be a possible crime threat, but a social threat as well.

Besides the issue of printing illegal drugs, individuals who want to earn easy money can also manufacture counterfeit drugs that produce similar effects, but have different chemical components from today’s controlled substances. Due to the drugs’ distinct chemical compositions, these counterfeit drugs may not be covered by current laws and would hence be technically legal. They might also be more dangerous than the controlled substances because less research is done to understand their chemical composition and discover the side effects of these drugs.

Compliance With FDA Safety Standards

All food, toys, cosmetic and medical products made with 3D printing technologies must comply with the regulations outlined by the U.S. Food & Drug Administration (FDA). How can we ensure that 3D printed foods fulfill all the necessary safety standards? Despite its promise, 3D printing is still relatively immature when it comes to safety and quality control standards compared to conventional food manufacturing process.

3D printed food is still at its early testing phase as researchers are trying to incorporate nutrition into the printed food. 3D printed food creates a new dilemma for the FDA because the authorities are unsure whether the current GMP and food reviewing procedures are sufficient and applicable to the 3D printing industry, or should new regulations be made, said Claudia Lewis, a partner at Venable LLP.

Currently, 3D printers are capable of printing pastries, desserts and burgers or even personalized food items and can cater to people with special dietary requirements. However, a lot of stakeholders in the 3D food printing industry are not fully aware that food elements have to be regulated. The food products will not get to market unless they get some sort of approval by the FDA. How the FDA decides to regulate the food depends on which category the product belongs to. For example, FDA regulations for beverages depend on whether the beverage is classified as a conventional drink or a dietary supplement. It is required at this point for the FDA to seek to understand more about the food industry and for the industry to ask the agency for guidance.

Ethical Considerations

3D printing has made its presence known in the field of medical science and technology. Through tissue engineering, 3D printing is utilized to build biological substitutes that mimic human bodily tissues and can be used to heal wounds or restore failing organs.

Traditionally, tissue engineering starts by taking a small biopsy from a patient. The cells from the biopsy are isolated, expanded and seeded on a natural or synthetic scaffold. After the cells differentiate and proliferate in the scaffold, the resulting tissue construct is transferred to a bioreactor for it to mature before it can be used for transplantation. Through this approach, researchers have successfully printed the trachea, ear cartilage, urinary bladder and so on. However, this approach is still limited in terms of accuracy and reproductibility that can be achieved as more complex multicellular

structures with vascular network integration has to be built (Lucas & Spiegel, 2015).

The innovation in bioprinting is relatively new and there aren't many similar procedures with which to compare them. There aren't many prior case studies or statistics to be used for weighing the possible contradictions and risks. Patients have to fully trust the work of the biomedical engineers and doctors. Besides, the cost of the procedure will be very high, hence raising the question of medical procedure coverage by health insurance companies. Is this procedure worth the cost and risks when it is still at its early stages of research and implementation?

Still at its early stages of research, it is only ethical for the researchers to consider the patients' safety in using bioprinted tissues or organs. The safety of the patient throughout the healing process is the utmost concern with bioprinting (Lucas & Spiegel, 2015).

Though there are biomedical engineers who have successfully printed various body parts, it will take a considerable amount of years before commercialized printing of compatible organs could take place. Currently, only microtissues can be printed (Varkey & Atala, 2015). The Food and Drug Administration will have to screen through all bioprinted tissues and organs for effectiveness and safety, and also weigh the pros and risks involved.

A number of regulatory laws will need to be cleared before the first lab-printed organ becomes commercially available. Technological advancements in terms of software and advances in medical science and technology are needed before the application of bioprinting can occur in a widespread manner (Varkey & Atala, 2015).

SOLUTIONS AND RECOMMENDATIONS

Technical problems can be easily resolved by creating a 3D printer that is of higher sophistication, is durable and cost-efficient. More raw materials can be sought after and test-run for printing a wider range of objects in the future.

The U.S. government should implement copyright laws for CAD design files specifically on those of firearms. Though it is legal to own a firearm, the government can pass a law that prohibits the manufacturing of firearms for selling purposes. The law should also implement a strict screening of eligible firearm owners before gunsmiths start selling to them. It is reasonable that only sound-minded and good-intentioned folks are capable of handling firearms for logical reasons. The authority of printing drugs should be strictly given to registered medical institutions, practitioners and researchers to ensure quality control. Law enforcement will have to alter its investigation methods for drug crimes.

Furthermore, in terms of 3D printed food, the FDA must ensure that all food printed should adhere to the safety standards. Food printed has to be edible and contains nutrition readily absorbed by the human body.

Lastly, 3D bioprinting should be ethical by taking care of the patient's safety and concern (first and foremost). More tests has to be run in the field of organ printing to ensure maximum compatibility of cells and functioning after an organ transplant.

FUTURE RESEARCH DIRECTIONS

3D printing of hybrid objects is still an under-researched topic as most of the research done is on single-raw material printed products. The future of 3D printing would be promising if objects that require different raw materials for different functioning parts can be printed completely without the need of product assembling.

Another interesting field for research is 3D printed food. Currently, there isn't sufficient research that ensures the safety of 3D printed food in compliance with the regulations outlined by the FDA. Once 3D printed food passes the FDA regulations, they can start to be produced commercially and should garner great interest in the market.

CONCLUSION

3D technology will continue to evolve. Many stakeholders are adopting it due to the benefits it promises. A technology will prove to be useful if it falls into the right hands. Though 3D printing technology is used in weapon manufacturing, it is also being used to improve the lives of mankind. In the future, 3D printing will most probably be used to print human organs. An issue of concern is raised regarding the possibility of printing 3D drugs, through the assembly of chemical compounds at a molecular level. In the future, patients can print medicine on their own. It is only hoped that with regulations, the potential of 3D printing technology can be harvested for good and not for worse.

KEY TERMS AND DEFINITIONS

Additive Manufacturing (AM): The process of making 3D objects by applying layer upon layer.

CAD Design File: Stands for computer-aided design file; used by engineers or architects to create technical illustrations.

Elephant Foot: The base of the model is slightly bulging outwards.

Friction-Weld: A welding process that generates heat through mechanical friction between workpieces to fuse materials.

Gunsmithing: The act of making, selling and repairing firearms.

Pillowing: Bumps or holes are present on the top surface of the printed model.

Post-Processing: Furbishing or decorating stage of the printed model.

Rapid Prototyping: A set of techniques used to quickly fabricate a scale model of a part using 3D CAD data.

Scalable Production: A production that can cope and perform under an expanding workload.
